PROSPECTING IN NOVA SCOTIA.

That a radical change of methods is necessary to success in prospecting for gold in Nova Scotia is evident. The superficial extent of the province's gold-bearing rocks is estimated at between 3,000 and 6,000 square miles. The unit of land held under lease or prospecting license is an area—a space 250 feet by 150 feet. During the year 1910 work was confined to 95 areas.

Over a considerable period of years not more than 315 areas in all have been prospected or mined. At the close of the past year there were held either under license or lease 31,470 areas. Thus, placing the total gold-bearing territory at 3,000 square miles, we find that only about one-seventieth part, or 42 square miles, of the possible field has been taken up. An inconsiderable fraction of these holdings has been prospected, and a very much smaller portion mined.

These facts furnish food for thought, especially when considered in conjunction with the actual position of mining and prospecting. These conditions were illuminatingly touched upon by Mr. W. H. Prest in a paper read before the Mining Society of Nova Scotia. Mr. Prest points out the vital need of a practical knowledge of geology in prospecting a country like Nova Scotia. Familiarity with local conditions is, of course, a sine qua non. "Local experience is just as necessary," says Mr. Prest, "is just as necessary to the skilled mining engineer as it is to the prospector. The lack of practical knowledge on the part of our scientific men is only equalled by the lack of scientific knowledge on the part of our practical men." With this opinion we heartily agree. Nothing is more needed than an adjustment as between the empirical worker and the academic observer.

The day has passed when the man who "putters round the woods with a pick" can be considered a prospector. The complications of glacial and post-glacial geology must be studied and understood. The old method of uniformly tracking rich pieces of drift north is based upon insufficient knowledge. Nothing is more wasteful than indiscriminate trenching. Heavy work of this kind must be guided by close study of glacial and post-glacial action. This point is well illustrated by Mr. Prest from instances in his own experience.

Moreover, the haphazard manner in which preliminary work is undertaken is so costly that much discouragement has resulted therefrom. Mr. Prest suggests many possible and practical economies.

Two concluding paragraphs demand quotation: "I refuse emphatically to believe that there is any such thing as failure in prospecting in Nova Scotia, providing the money and practical knowledge are forthcom-

ing. . . We want geology, but only its most practical side. We want labour, but only its intelligent use; and last, but not least, we want solid financial backing."

STATISTICS AND CONSERVATION.

No one mineral commodity is subject to more extraordinary waste in mining, storage, transportation, and consumption than coal. In Nova Scotia, for instance, it can be proved that a large percentage of coal that was once available in the mine is now of no commercial value to the owners. Also there has been large waste through deterioration in storage. The same applies to our western collieries.

Both in Canada and in the United States the wasteful bee-hive even yet obtains—and for this there is yet good reason. The remedy for this condition can be only applied in homeopathic doses. No sweeping change is possible. But it is certain that the bee-hive will gradually be superseded by the retort oven, as witness the fact that 6,254,644 tons of coke were made in by-product ovens in the United States during 1909, while ten years ago the production was 1,075,727 tons. Some significance also may be attached to the fact that whereas in 1880 an average of 3,140 pounds of coal was used in making one ton of coke, only 3,020 pounds being used per ton of coke in 1909. These figures, are taken from Dr. E. W. Parker's report to the U. S. Geological Survey. Dr. Parker attributes this improvement entirely to the increased use of retort ovens.

Many more facts could be adduced from the same report. Our point, however, is that the cause of conservatism is definitely strengthened by means of carefully compiled statistics. Coal is at once our most important and our most largely wasted natural resource. Every unmined ton is appreciating yearly in value. We have only a vague idea of where we stand, of how large our reserves are, and of how enormous our waste. There could well be established at Ottawa an off-shoot of the Mines Branch to guard our natural stores of fuel.

THE WESTERN COAL STRIKE.

The strike of coal miners in Alberta and eastern British Columbia was declared on April 1st. Not less than 7,000 men are directly concerned. About 5,500 of these are members of the U.M.W.A. The mines that are closed produce an annual aggregate tonnage of about 4,300,000 tons. The suspension of coal production naturally entails the cessation of operations at the mines and smelters of southeastern British Columbia. Thus the copper industry of the west, giving employment to probably 4,500 men, will be temporarily closed.

The smallest item in all the train of suffering that strikes bring is loss to the investors. The largest is the misery that is brought upon the families of the thousands of workers directly and indirectly affected. A protracted strike breeds crimes of violence. No one can foresee the final outcome. To our mind the str is a grotesque anachronism. That it should still permitted in this country, despite our elaborate p ventive machinery, is tragical.

Already many of the unemployed miners are mov to the coast in search of employment. Soon the ca less good-nature that characterizes the inception hostilities will be replaced by rancour and open hos ity. The longer the life of the strike, the less will t mischievous organization, the U.M.W.A., be able carry out its pledges of financial support. When pinch of short rations is felt then also is felt the des for blood. The miserable drama, whose closing sc is even now being enacted in Nova Scotia, is evide a-plenty of the moral irresponsibility of the U.M.W.A leaders. To them the imposition of easily avoida hardships upon numbers of women and children i negligible incident.

In the present crisis the attitude of the Departm of Labour is not reassuring. With some regret we led to believe that the Hon. Mr. King fears to give Lemieux Act a thorough trying out. We hope t this belief is not well-founded. But it is quite appar that the U.M.W.A. intends to have its own way and flout openly any efforts of the Department that not in accord with U.M.W.A. ambitions.

Whether there shall be or shall not be "open-sho" is nominally the main issue. In reality, the objectiv the U.M.W.A. is supreme control of the coal-min situation in the west. How catastrophic such an ev tuality would be, we can judge by results in the e

In any rational and continued movement towa better conditions of work and living the coal mi of Alberta and British Columbia will have the m support of the Canadian public. In following the l of vicious foreign demagogues the miners lose all cl upon the sympathy of their fellow citizens.

UNTECHNICAL WRITING.

In the course of our duties we are called upon read a large number of professional reports and a c siderable volume of correspondence. Naturally th documents vary through a tremendous range of m demerit, and awfulness. In the main it is safe to s sert that hardly one report out of ten is prop written. Even the tenth, excellent as it may be i technical sense, falls short of what it might be bec of the careless use of the English language.

Undoubtedly many serious losses have been incu through the use of loose and ambiguous phrases. misplaced comma may alter the whole meaning sentence. Trivial typographical blunders may b ruin in their train.

As a signal example of obscurity we append a c of a letter received by a Canadian mining engin We can vouch for the authenticity of this letter. It has been reproduced as closely as possible in the im of the original. Here it is, and we defy our rea

arrive at the intentions of the writer:

Dear Sir I am droping you a line to see if
You care to Entertain a Copper &—Gold Prospect—
¾ of a
mile from Electrict Power line—4¾ miles from Rail-
road Station over good Wagon road—
there Was 93.242 of ore shiped
from there about 5 years ago—& it avriged $50.00 per to
& there Was Nothing. allowed:
them for the Gold & Silver—
the Prospectors left it to the Smelter Co—& they told
them the Gold—onley Ran from 50c. to $4.50 per ton
& the silver Was onley 60c. to 90c. per Ton & the
Prospectors—let it go for granted that it Was all true—
& they ware satisfyed With there ore as they ware
going $50.00 per ton out of it:
Now Here in the 60th there Was a shaft sank—100 ft—
deep & no difting there is about 18 in of good ore in
the shaft— & there is another Hole about 60 ft sank
some 40 years ago & no—drifting—in it—there is a
good showing in this Hole also More than 18 inches—
the fellows that owned. it: sank a hole about 50 ft
deep I think it was—& took out the 93.242.00 of ore
& shiped it they Cleaned out the other 2 Holes—& Had
a fine showing there. at that time: & I took Mr. L.
Lindsy of Los Angles Cal—there to see it.
they ware asking $50.000.00 for it then & Wanted
$5000.00 down before they would allow us to touch it
—Mr. Lindsy—told them he Would put 12 men to work
& prospect for 100-dayes & at the End of the 100-dayes
he Would give them the full $50.000.00 an he Would
give them. Whot ore he had taken out at his Expense
but one.
of the Prospectors was
held strong & Refused his offer—then We left it—
in about 2-Weeaks after that the owners fell out. quit
work: & shiped there ore & quit & Here about 9- monts
ago the fellow that Was—fair to deal With: traded:
His Partner out & I Can.
Now deliver it on a—2—years Working Bond—for
$2,000.00
No—money at all untill you have Prospected for 12.
months & if you are Not satisfyed at the end of the 12-
months pull off your Emprovements & quit.—if you
Want to go a head pay-half- of the $20.000.00 & go
ahead for 12 monts more then pay the bal—
Now there is but little to see untill the holes are
unwatered but it is No
Wile Cat & I feal—sure there is a good
Mine there & My offer—Sirtenly is Fair—
Would like to Hear from You
Yours—

TRANSVAAL MINING CAPITAL.

From returns recently furnished by the Transvaal Mines Department we learn much that will be instructive to those who seek to institute unwise comparisons between South African mines and those of undeveloped regions in this country. Of the 241 gold mining companies listed, 139 are on the Rand. Glancing at these latter, we find that 43 are dividend paying; 21 are producing ore but no dividends; 20 are in the development stage; and 55 are not working. Without the limits of the Rand there are but four dividend paying mines.

The net issued capital of the Rand mines aggregates roughly $309,000,000. The paying mines account for $165,000,000; the producing non-dividend mines, $50,000,000; developing prospects, $61,000,000; and dead mines, $33,000,000.

EDITORIAL NOTES.

Our readers are not to conclude that the illustrations representing Nova Scotian gold-mine scenes, published elsewhere in this issue, represent all that is to be seen. The province contains some admirably equipped plants, and numerous small modern stamp-mills.

Apart from scientific interest, the principal value in the reported discovery of diamonds in British Columbia lies in the excellent opening it gives for journalistic fireworks.

A custom that has survived too long is that of encouraging long-distance orators to torture us at official dinners. The annual dinner of the Mining Society of Nova Scotia, held recently in Halifax, was a noteworthy exception. At this event all speech-making, save only a short address accompanying the toast to the King, was done away with. Musical numbers took the place of the ordinary arid eloquence.

It seems highly probable that Canada will soon feel the grip, paternal or otherwise, of an explosives trust. The trust is an accomplished fact. The strangle-hold may come sooner or later.

The Board of Conciliation, appointed by the Department of Labour, decided in favour of the striking coal miners at Port Morien, Cape Breton. This decision will strengthen the hands of the miners. But it is remarkable how slightly the Department has been able to affect the grievous condition in Alberta and British Columbia, where thousands of miners have ceased work without even a colourable regard for the law.

The Porcupine boom has not gained the headway that brokers had hoped it would. The stock market is not over elastic. Not the prestige of the Bewick-Moreing people (of whom more particulars are obtainable in London than in Toronto), not the glamour of Heinze, nor yet the diffusive joy of the vendor suffices to create the wave. The press is, as a whole, praiseworthily careful.

The Cobalt Daily Nugget argues, with a large degree of reason on its side, that the Ontario Government should remit the excessive royalties that it has heretofore imposed upon certain mining enterprises in Cobalt. In its salad days the Government caught the fever that infected the whole country. It wanted to make money and make it rapidly. Now, however, such conduct would not be compatible with its larger dignity. But that same dignity would be enhanced were the Nugget's suggestions followed.

Correspondence

The Editor, The Canadian Mining Journal:—

Sir,—I am taking the liberty of writing this letter, to ask your opinion of a chemical reaction which probably might interest your readers, as it gives a simple, instantaneous method of restoring over-exposed blue prints at very little cost.

About two years ago, while making a number of blue prints, in a moment of curiosity I happened to pour some hydrogen peroxide over an over-exposed print. The print, which was burnt to such an extent as to be almost obliterated, at once assumed a rich blue colour, and the white lines came out with great intensity.

Since that time, in the southern office of the Republic Iron & Steel Company, I have continually used hydrogen peroxide to restore over-exposed prints, and have thereby saved many prints which would otherwise have been lost.

In fact, when it was desirable to make a very strong print, I have intentionally over-exposed and treated with H_2O_2, as the resultant was so far superior to ordinary blue print.

For my own satisfaction I have tried to read up the reaction and to the best of my knowledge the following represents the reactions:

To begin with, it is well to remember that ferrous salts yield with potassium ferricyanide, a deep blue precipitate of ferrous ferricyanide, popularly known as "Turnbull's Blue." This is the composition of the blue of the print, and it has the chemical symbol $(Fe_2(CN)_6)$.

Now, ferric oxalate, exposed to light, is reduced to ferrous oxalate, by the following reaction:

$$Fe_2'''(C_2O_4)_3 + light = 2\ Fe''C_2O_4 + 2\ CO_2$$

Then, the ferrous oxalate, thus formed, reacts with potassium ferricyanide ($K_3Fe_2(CN_6)$) to form the ferrous ferricyanide, cited above. The following reaction explains this change: $3\ Fe_2C_2O_4 + 2\ K_3(Fe(CN)_6) = Fe_3''(Fe(CN)_6) + 3\ K_2C_2O_4$.

The H_2O_2 then reduces to ferrous form very rapidly the ferric molecules that had either not been reduced at all, or else had undergone subsequent oxidation. When forced to reassume the ferrous form by the action of H_2O_2 these molecules were immediately attacked by potassium ferricyanide to form additional "Turnbull's Blue," thereby intensifying the print.

In using the "peroxide" the print is first washed in cold water and then spread face upwards on a table where a few drops of 1 : 4 H_2O_2 solution are dropped on its surface. The hydrogen peroxide solution is spread over the surface of the print either with the hand or a small sponge, the print again washed in cold water and hung up to dry.

Yours sincerely,
Gerald Dob[illegible]

MINING IN NOVA SCOTIA DURING 1910

Notes compiled for the Canadian Mining Journal from the Annual Report of the Department of Mines:

Nova Scotia Mineral Production.
Year Ended September 30th, 1910.

Mineral.	Quantity.
Coal raised (gross tons)	5,477,146
*Iron ore (net tons)	52,640
Pig iron made (net tons)	341,674
Ingots steel made (net tons)	409,663
Limestone quarried (net tons)	483,100
Patent fuel (coke) made (net tons)	493,167
Gypsum quarried (gross tons)	322,974
Building stone, quarried (net tons)	8,503
Bricks, made	21,305,500
Drain-pipe, made (feet)	974,819
Grindstones quarried (net tons)	325
Gold bearing ore mined (net tons)	49,557
Gold produced (ounces)	10,675
Manganese ore (net tons)	25
Copper ore (net tons)	nil
Antimony concentrate (net tons)	203
Moulding sand (net tons)	180
Scheelite (net tons)	75
Sulphate of ammonia (net tons)	3,622

*Iron ore imported, 705,351 net tons.

COAL.

During 1910, there were 4,896,896 tons of coal [illegible] an increase over 1909 of 281,183 tons. The total [illegible] duction was 5,477,146 tons, colliery consumption [illegible] counting for 515,720 tons.

In Cumberland County the total output was 27[illegible]6 tons, as against 542,040 for 1909. The Maritime [illegible] Railway & Power Company, with 161,843 to its [illegible] was the chief producer, the Cumberland Railway [illegible] Coal Company's output being largely reduced on account of the protracted strike.

Pictou County's production was 629,599 tons, a slight falling off as compared with 1909. The producers were the Acadia Coal Company and the Intercolonial Coal Company.

In Inverness County, 364,104 tons were raised, the Inverness Railway & Coal Company contributing 107,257 tons, and the Port Hood-Richmond Railway & Coal Company the balance.

Cape Breton County output was 4,205,131 tons, as compared with 3,634,392 tons during 1909. The Dominion Coal Company, with 3,244,754 tons, and the [illegible] Steel & Coal Company, with 836,348 tons, accounted for the great bulk of the tonnage.

11,001 persons were employed during the year

1910

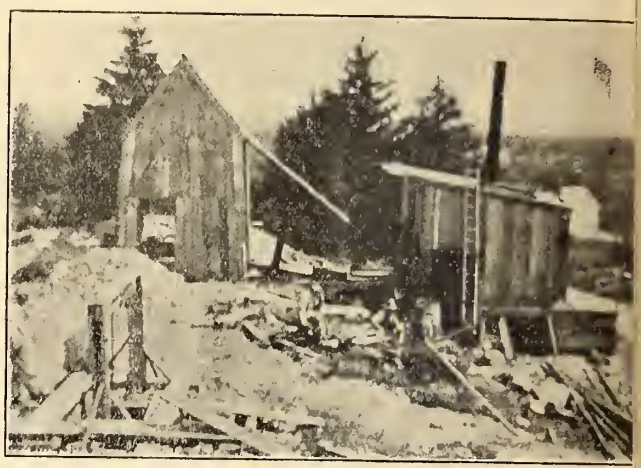
GOLD.

The total yield of gold was 10,675 ounces recovered from 49,557 tons of gold, a figure slightly below that of the previous year. The average yield—an average that is arithmetical rather than physical—was $4 per ton, higher by 4 cents per ton than that of 1909.

One serious blow to the industry was the temporary stoppage of work at the Richardson mine at Goldboro (Guysboro County) due to a cave-in of the old workings.

Twenty-five small concerns operated during the year. A considerable amount of prospecting was done that should affect favourably the results for the current year.

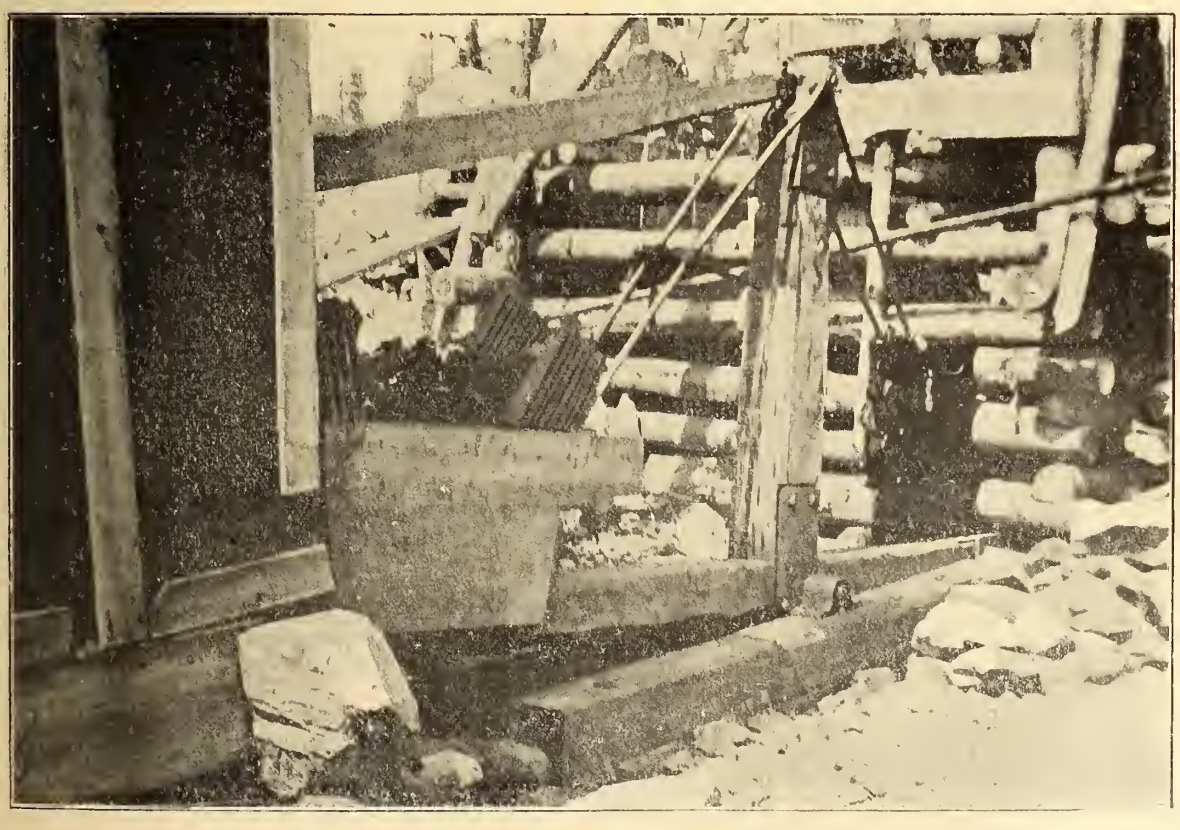
GUYSBORO COUNTY—The New England Mining Company, working the Richardson mine, recovered $7,297 in gold from 36,940 tons of ore, an average of $2



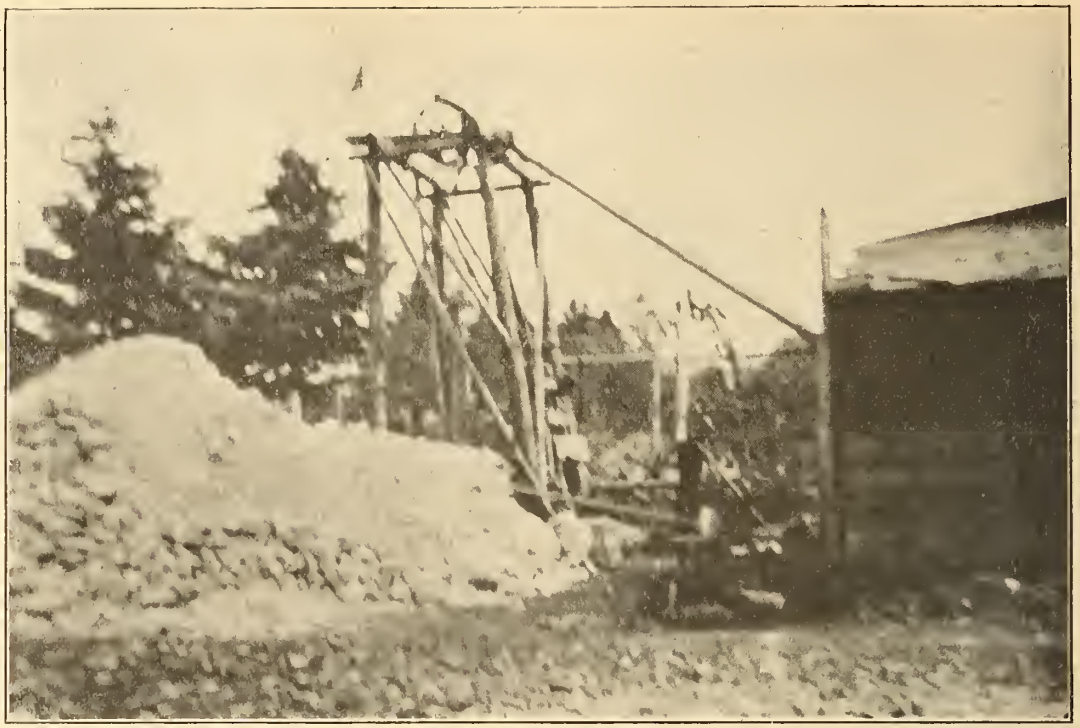
Montagu—Typical small gold working

Montagu—Veteran Miner standing behind remains of stamp-battery foundations

Montagu—Old shaft 25 feet by 6 feet sunk about 120 feet



Cornish pump at Montagu



Headframe and dump

per ton. 715 ounces were extracted from 956 tons of concentrates by bromo-cyanide treatment. 529 tons of arsenical concentrates were made and shipped to Swansea. The Richardson has yielded about $1,000,000 in its 18 years of life.

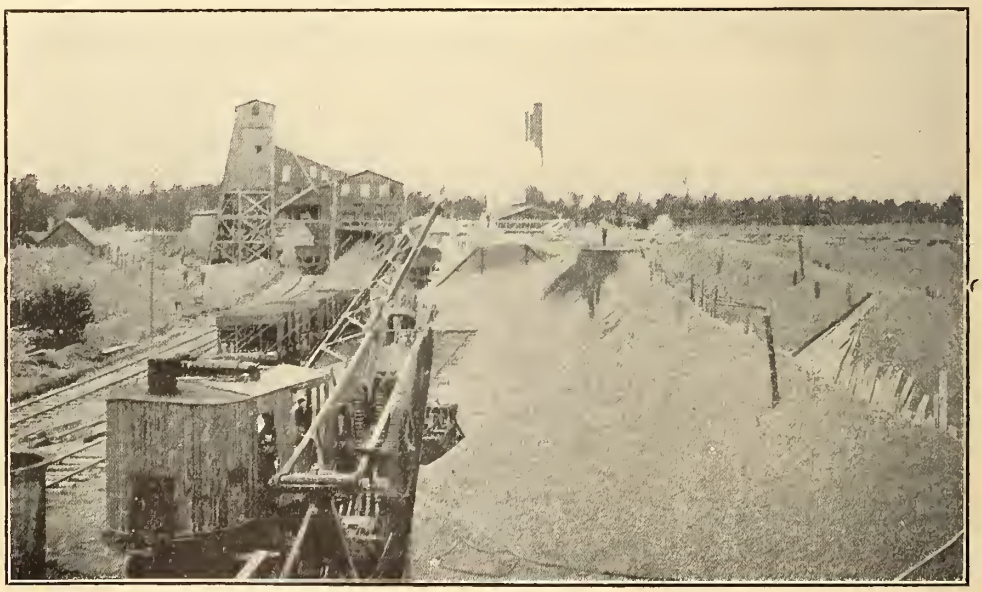
Halifax County—At Killag and Salmon River small prospects were worked. At Tangier, the Dominion Mining Company extracted 866 ounces of gold from 3,090 tons of ore. At this plant hydro-electric power is used.

The Caribou Gold Mines, Limited, at Caribou, won 273 ounces from 409 tons of ore. Fraser and McLeod, working at Fifteen Mile Stream, extracted 148 ounces from 180 tons of ore. Other small enterprises reported unimportant returns. The Petpiswick Mining Company, under the management of Mr. G. J. Partington, did much preparatory work at Lake Catcha. At Ol ham, the Oldham Mining Company, E. H. Brenna manager, won 2,481 ounces of gold from 1,260 tons ore, the average per ton being $37.41, taking gold $19 per ounce.

Lunenburg County—The Gold River mine of t Chester Basin Gold Syndicate, managed by A. B. St wart, was closed in February, 1910. The Uniac Min & Power Company, Limited, won 58 ounces from tons of ore.

Queens County—At Malaga Barrens, the Ponho Mining Company, under the supervision of W. J. Pris mined and milled 776 tons of ore yielding 326 ounc The mine was closed in June. More capital is require

Hants County—Representatives of Mr. M. O'Brien, operating the property formerly belonging



Torbrook Iron Mine, west shaft

the Pictou Development Company, mined and milled 1,834 tons of ore yielding 624 ounces.

IRON.

During the year the amount of iron ore mined in the province increased from 10,000 tons to 52,640 tons. This quantity was produced at the Torbrook mines of the Canada Iron Corporation, Limited. Shipments totalling about 11,000 tons were made to Pennsylvania and to Glasgow.

705,351 tons were imported by the Dominion Iron & Steel Company and the Nova Scotia Steel & Coal Company.

ANTIMONY.

No antimony was mined at the West Gore mine of the West Gore Antimony Company. The dump ore was milled to the extent of 5,565 tons, yielding 203 tons of concentrates.

MANGANESE.

25 tons of high-grade manganese ore were shipped from New Ross by the Nova Scotia Manganese Company. Work is being pushed vigorously and further shipments are being made.

TUNGSTEN.

75 tons of high-grade tungsten ore were shipped from Scheelite, Moose River, Halifax County. The mine is now under the management of Mr. Victor Hills, an experienced Colorado mining engineer. Many new veins have been discovered and development has brought much ore in sight. Regular shipments will commence this summer.

GYPSUM.

The growing gypsum industry had a good year, 322,774 tons being produced. Only 10,500 tons were used in the manufacture of gypsum products in the Province, the balance being shipped to the United States. 40 men were employed. Eight concerns operated.

The Mining Society of Nova Scotia

Nineteenth annual meeting at Halifax, March 29th and 30th, 1911.

The meeting convened at 10 a.m. the morning of March 29th, Mr. T. J. Brown (Manager, Nova Scotia Steel & Coal Company's collieries at Sydney Mines) in the chair. The morning session was taken up with the following business:

Reading of Minutes of last Annual Meeting.
Election of new members.
Report of Secretary.
Report of Treasurer.
Report of Librarian.
Report of Council.
Appointment of Scrutineers.
Report of Special Committee regarding Legislative matters.

Wednesday Afternoon.

The President gave an address and also read a paper entitled "The Great Black Cities." In this paper he described the underground workings of a mine, drawing comparisons between it and the ordinary city life. This was followed by two moving picture films—one illustrating the workings of an underground mine, explosions, care for the injured, etc. The other film showed the manufacture of steel from the open-hearth to the finished article.

Mr. C. H. Wright (Manager of the Halifax branch of the Canadian General Electric Company) then read a paper on "Electrical Apparatus for Mining." This paper was illustrated by a number of very fine lantern slides.

Mr. C. J. Coll (General Manager, Acadia Coal Company, Stellarton, N.S.) followed with a paper entitled "Use of Permitted Explosives in Coal Mining."

After both these papers there ensued lengthy discussions.

This completed the afternoon session.

Wednesday Afternoon.

The Annual Banquet, which is always an event of prime importance, took place at the Halifax Hotel. Among the invited guests were:

Lieutenant-Governor MacGregor.
Hon. A. K. McLean, Attorney-General of Nova Scotia.
Hon. G. H. Murray, Premier of Nova Scotia.
Hon. William Templeman, Minister of Mines.
Hon. Christopher Chisholm, Commissioner of Public Works and Mines.
Members of the Geological Survey, Ottawa.
President of the Canadian Mining Institute.
President of the American Mining Institute.
President of the Nova Scotia Society of Civil Engineers, etc.

Thursday Morning.

Prof. E. A. Holbrook (Mining Department, Nova Scotia Technical College, Halifax) read a paper entitled "Modern Gold Mining Practice and its Application in Nova Scotia."

Mr. John Preston (Manager, Colliery of Nova Scotia Steel & Coal Company, Sydney Mines) read a paper entitled "Description of Light Weight Motor Driven Reciprocating Pump."

Mr. W. F. Jennison, C.E. (of Truro, N.S.) read a paper on "Gypsum." This is the first paper on gypsum that was ever read before the Mining Society of Nova Scotia. It was listened to with keen appreciation and was interestingly discussed.

Mr. W. H. Prest (of Bedford, N.S.) read a paper on "Prospecting in Nova Scotia." Mr. Prest's thoughtful paper is referred to in the editorial columns of this issue.

The meeting then adjourned until 2.30.

Thursday Afternoon.

Mr. H. E. Coll (Manager, Acadia Coal Company, Stellarton, N.S.) read a paper entitled "Regulations Governing the Use of Explosives in Coal Mines." In reading this paper, Mr. Coll used paraphernalia to illustrate the safe handling of explosives, etc.

This paper was followed by the following:

Dr. Ora W. Knight (State Assayist for Maine, U.S.A.) "Research Work on Certain Nova Scotia Gold Ores."

Mr. G. J. MacKenzie (Mines Instructor, Westville, N.S.) "The Coal Dust Problem."

All these papers were discussed and votes of thanks passed those furnishing them.

The President then read the result of the ballot. A vote of thanks to the retiring President was moved by Mr. C. J. Coll, and seconded by Mr. G. J. Partington.

The meeting broke up singing "For He's a Jolly Good Fellow."

This meeting was probably one of the best in the history of the Society in point of papers read, but on account of the lateness in the month, which was un-

avoidable, a number of the members found it impossible to attend.

Mr. D. B. Dowling, of the Geological Survey Department, Oottawa, read a paper on the "Coal Mining Industry of Alberta and British Columbia.

Mr. J. C. Murray brought to the notice of the meeting the work being done by the Special Committee of the Canadian Mining Institute in codifying the mining laws of the Dominion.

The officers elected for the current year were:

President—G. J. Partington.

First Vice-President—Prof. Sexton.

Second Vice-President—Thos. Cantley.

Council—C. E. Starr, Hiram Donkin, R. H. Brown, H. E. Coll, A. L. McCallum, A. A. Hayward, Hon. R. Drummond, G. W. Stuart, John Johnston.

OUR EUROPEAN LETTER

British mining markets dull — Lowering cost of getting British coal — Some comparative expenses—Royal Commission on Mines and its opinion on ventilation —Salt Union and the Bowman-Hodgkinson process—A submersible electric motor for pumping out flooded mines—Shaft sinking against water by cement injection—Russia's backward gold industry.

(Exclusive correspondence of Canadian Mining Journal.)

London, March 18th, 1911.

Mining descriptions on the British share markets continue to make only a very poor show, there being very little demand on the part of the public and nothing to stimulate the demand. The best that can be said of most of the big features such as South Africans is that the declines in quotations this year have been small. South Africans particularly have suffered in response to the persistent liquidation in Paris where several agents de change have risen. Tin mine shares preserve a certain buoyancy but the fluctuations in the price of the metal do not conduce to buying.

So far as British coal mining is concerned that interest which is always aroused in any new method which would have the effect of materially lowering the cost of getting British coal has been excited in connection with a paper recently read by A. E. Booth before the Midland engineers. The contents of the paper are all the more significant, taken in conjunction with evidence brought before the departmental committee appointed to inquire into the working of the special rules. For instance, one passage given in the evidence by D. M. Mowat, general manager of the Summerlee Iron Company, of Coatbridge, Scotland. This gentleman said: "There is no doubt that a coal-cutting motor was one of the machines which had improved tremendously in the last ten years. Ten years ago they had a breakdown once a month. In Scotland there are practically no compressed air machines being installed. Electricity has been in use for thirty years, and we have never had an ignition of gas arising therefrom." It was also noted that five more cutters driven by electricity were being put in, and a further installation was in contemplation. In other parts of his evidence, however, he explained that the Scotch coal mines he was referring to were not what is known as of a fiery character —that is to say, there were never any great outbursts of gas sufficient to cause big explosions; but, nevertheless, the fact that electric power has been employed with apparent success for so many years in Scottish coal mines is of great significance.

At the outset of Mr. Booth's paper he said that machine-cutters resulted in a higher output from a given length of "face." He then proceeded to describe at great length certain new types of conveyors, which are designed for use on thin seams of coal in conjunction with machine-cutters. The features of some of these contrivances have hitherto been quite unknown in coal mining practice. He furnished a great mass of technical details dealing with the mechanism of the various types of conveyors, which would be quite out of place in these columns. One of the points which he emphasized was that the trials of these devices had been the most successful where the apparatus had been especially designed for the local conditions.

In speaking of the advantages of these new methods he fully admitted that the changes involved in the organization of a coal mine by the introduction of mechanical cutters and conveyors created many difficulties for the management, but he strenuously argued that if the problem was approached with determination and perseverance a satisfactory result could be obtained. Not the least among the difficulties surrounding the introduction of new machinery in coal mines was that connected with the labour question. The machine-cutting and conveying installation made it necessary to allow a group of men to work together under the instructions of a foreman, in parts of the mine somewhat remote from other operations. The character of the whole arrangement and the kind of discipline necessary to carry on the work with success, giving the new machinery a fair chance of justifying itself, have to be carefully thought out, and the personal element duly allowed for. Under adequate and good management, however, it was shown that considerable economies could be effected in the winning of coal, and particularly so when the operations were on thin seams.

As showing the actual comparative cost of working a 2-foot, 8-inch seam as between three systems, the following figures were cited:

Working Costs per English Ton.

	By hand.	Machine cutting.	Coal cutting and conveyor
Getting, timbering, etc..	$0.48	$0.30	$0.22
Stonework..	.16	.14	.06
By-work..	.08	.10	.04
Sundry costs	.10	.10	.04
Moving conveyor..	...	...	.06
Total per ton	$0.82	$0.64	$0.42

All over the United Kingdom the great thick seam of coal are being steadily exhausted, and more and more attention has, perforce, to be given to the thinner seams. Without going into the technique of the matter, it may be noted that with the old-fashioned handwork the getting of coal from thin seams is full of difficulty, besides being essentially more costly, and

therefore, in the majority of cases, commercially impracticable. But, assuming that the mechanical methods described in this paper prove to be sound and practicable in actual working, the whole aspect of the coal situation in this country will be profoundly modified. The commercial difficulties connected with the thin seams will largely disappear, and the available supply of good coal will be immensely increased.

Also, according to Mr. Booth, the use of the apparatus he described would bring about a permanent increase in the percentage of "round" coal, which follows upon the use of face conveyors. This appears to solve one of the ever-present and pressing problems in the working of all thin seams—namely, a reduction in the amount of small coal.

The third report of the Royal Commission on Mines was issued on March 16th. In their second report the Commissioners expressed the opinion that it would be desirable to have such a standard of ventilation as to prevent the appearance in any open and readily accessible position of a fully-formed "cap" on the lowered flame of an ordinary safety-lamp, burning the oil in common use, and that the men should not be allowed to work or pass where this standard is exceeded. Since that time they have studied the subject more closely and now deal with the percentage of gas which should be allowed by this standard, and recommend that it should be made law that no men shall work or pass in the ordinary course of their employment in places where there is more than 2½ per cent. of gas in the general body of the air. If a higher percentage is found, no one ought to go or work there, except under special supervision, for the purpose of removing the excess of firedamp or otherwise securing the safety of the mine. Such an enactment, the Commissioners think, ought specially to point out that this provision is not to be taken as a standard of ventilation, but is in addition to the existing duty of adequately ventilating the mine. For mines worked with naked lights, a similar rule is proposed, with the substitution of 1¼ per cent. for 2½ per cent.

At the annual meeting of the Salt Union, held on March 17th at Liverpool, good results were recorded despite the over-production in the trade. Chairman J. H. Cox naturally referred to the Bowman-Hodgkinson patent, concerning which so much matter has appeared in the press lately, but he refused to commit himself to any expression of opinion regarding the value of this process as the trial tests have not commenced. However, he asked the shareholders not to listen to all the "tittle-tattle" that went on with respect to this patent. Exhaustive tests are to be made at the Northwich works of the Salt Union, and it may be held that as an option has been acquired over the United Kingdom rights, the process is regarded seriously.

As readers of the Canadian Mining Journal will be well aware, the inventor claims to increase enormously the output of salt from a given quantity of brine, and at the same time, as might be expected, to reduce the operating charges correspondingly. One is inclined to wonder what is to become of all the salt which is threatened to be produced by so fundamental a change in the volume of output, but apparently the reply to this query is that lower selling prices will promote consumption—particularly in the East. Whatever may occur in this connection, however, it is clear that important developments are impending in the salt industry, and on the whole the tendency appears to be towards increased profits for the Union.

Experts of the British and other Governments inspected on March 8th a demonstration of the Macdonald submersible electric motor in London. It is claimed that this invention will revolutionize the methods of pumping out flooded mines or sunken ships, as the motor works equally well whether sunk in water or running on dry land, while it can be employed for working coal-cutting machines without the slightest danger of "sparking." The type of motor working on March 8th was of 10 h.p., and it is capable of discharging 30,000 gallons per hour to a height of 30 feet. It ran without a hitch during the hours of observation. Captain Young, of the Liverpool Salvage Association, which has done great feats in the raising of warships and other vessels, expressed enthusiasm about the invention. "There is, as you know," he said, "an agitation against the use of electric motors in coal mines, especially in working the cutting tools. This motor can be placed in a tank of water and attached to the machine and the switches, and, being thus submerged, does away entirely with the danger of 'sparking,' Again, ordinary electric pumps in a mine are rendered useless by a rush of water, as in South Wales recently, but this motor works in water, though it is unenclosed except for a light covering to keep floating debris from the working parts. From my own point of view, that of salvage, it will be of importance as a first-aid pump, as it requires no suctions, no primings, and can be lowered in a chain sling and commence operations immediately."

The Poetsch freezing process for the sinking of shafts in water-bearing ground is a well-known one. There has been now developed in France, in the chalky formation of the Pas-de-Calais coalfield, the process of shaft sinking against water in fissured ground by injections of cement. This is suitable for any fissured water-bearing rocks, but is of no use for a soft-running ground such as quicksand.

The principle is that a number of boreholes of suitable dimensions are sunk at equal intervals in the form of a ring surrounding the proposed site of a shaft. Cement and water injected through these bore-holes by means of a force-pump find their way into all the cavities and crevices of the ground surrounding each hole, in which the cement sets. As the cement from one hole penetrates the rocks surrounding it, that coming from the adjoining hole is encountered and a cemented, water-tight wall is formed round the proposed site of the shaft. In this way it is possible to get rid of the water troubles that occur in the process of sinking. The equipment for the process is small and inexpensive as compared with that required for making an ice wall by the Poetsch process, besides which, when once the cement has set, the work of the plant is finished, whilst with the Poetsch method the machinery has to be kept at work until the shaft has been sunk and lined, a considerable extra expense being thus incurred. As a result of these savings, the cost of sinking by cement injection is only about one-third that of the Poetsch process. The practical advantage is that water is almost completely shut out, and a masonry lining, if necessary, is made more secure, though the solid wall of concrete makes the lining almost superfluous. The danger to shaft sinkers is greatly lessened, as they have not to cope with continual water troubles when sinking, and, in the event of repairs to shaft lining being necessary later, the existence of the permanent cement wall practically shuts out all water from the shaft, whereas with the Poetsch

freezing process the water is held back only by the tubbing.

Although in the past twenty years Russia has increased her production of gold by 50 per cent., yet this is nothing in comparison with the increase in other parts of the world. The reasons are found for this backwardness of Russia in a production for which nature has particularly fitted her in the following: Russia lacks roads and railways, and cannot get at her gold with the facility necessary; she is hampered by legislative and administrative orders that put serious obstacles in the way of private ventures, and she has not the superabundant capital required to place the industry of gold-getting on a satisfactory footing to compete with other goldfields the world over.

The necessity of paying closer attention to the gold-wealth of Russia can be argued on the following lines: Gold alone of all the industries is capable of creating colonization in waste places of the kind found over a great part of the regions of the empire known to be auriferous; it is an industry that is not subject to the same uncertainties of markets and prices as other productions of all kinds are; on the contrary, it creates markets for all other goods, for it has been estimated that for every unit of gold got out of the earth from 2,000 to 2,500 units of other goods must be provided for consumption by the workers. Owing to redundant harvests, Russia is now exceptionally well situated in the matter of gold, which continues to come into the country in return for grain and other commodities; but this cannot be reckoned on to last forever, and Russia, with her gold value, must get more gold out of her own territory if she is to avoid difficulties in maintaining her gold value.

The measures proposed in this direction are various. New laws for Siberia, involving either some form of local self-government or the placing of administrative powers in the hands of the gold-getters, whose organizations, in fact, do administer for all practical purposes no small part of the wilder districts of Siberia and the regularizing of the practice of "gold running," which at present is illegal, but so profitable as rarely to incur penalties at the great distances from the seat of authority at which it is practised. The "gold-running" is treated as highway robbery, and most severely punished. In all other countries it is called "prospecting."

LABOUR DIFFICULTIES IN WESTERN COAL DISTRICTS

By E. Jacobs.

The Canadian Mining Journal has already published a list of the various companies concerned in the labour difficulties affecting the collieries of the Crow's Nest Pass district of British Columbia, those situated near the Canadian Pacific transcontinental railway in Alberta, and most of those in Alberta about Lethbridge and westerly along the Crow's Nest Railway. A list of the twenty-five locals comprising District No. 18 of the United Mine Workers of America was also printed, and detailed information was given showing the preliminary proposals of the representatives of the miners, together with the reply thereto of the Western Coal Operators' Association consisting of sixteen coal mining companies operating on the several districts above-mentioned. Further, the chief obstacles to progress towards making a new agreement between the operators and the U.M.W.A., the latter representing the employees—namely, the question of open or closed shop, the check-off system, and the discrimination clause, were briefly stated. Since then negotiations, which on March 9 were postponed for eleven days, have been resumed, but unfortunately without any agreement having been come to, for on March 24 the conference was "declared off," and the representatives of the mine operators and miners dispersed. The situation was shortly indicated in a message from Calgary, where the conference had been held, to the "District Ledger," the union miners' newspaper, published at Fernie, B.C. This brief message was: "Negotiations at an end. Adjourned sine die."

There was no discussion of the rates of wages to be paid in future to the various workers, for notwithstanding that at different times, first the operators and then the miners suggested that consideration of the wages scale be proceeded with, this was not done. The main issue was the check-off system, and in relation to this both sides remained firm—the miners' representatives insisting on an effective check-off system being provided for, and the operators refusing to concede the point to the extent asked on behalf of the miners.

What Happened in 1909.

A review of matters connected with proceedings 1909, when the agreement which has just expired w made (but not until after the mines then represent by the Operators' Association has been idle thr months), will perhaps make the position to-day mo clear. In March, 1909, the agreement made in 19 being about to expire, a conference was held at Ma leod, Alberta, between the operators and represent tives of the employees, and all differences adjusted, that the agreement reached was referred to the m employed at the various mines for their approval or r jection, with the result that a large majority in favo was reported. The then president of District 18, U. W.A., Mr. Frank H. Sherman, who had been too ill take part in the conference at Macleod, however, d not approve of the agreement, which permitted "op shop" at the several collieries concerned, and contain a "Discrimination clause" which effectually weaken the union in its efforts to prevent non-union men wor ing in the coal mines or at the coke ovens, so he a the secretary for District 18 called a strike and order the men to stop work at the expiration of the old agr ment. The main object of this arbitrary action was compel the other operators to yield to the union's d mands, as had the Crow's Nest Pass Coal Compa which had withdrawn from the Operators' Associati and made its own agreement with the miners, w were granted the check-off system, so vital to the su cess of the union locally, and, too, there was in th agreement no discrimination clause to restrain t union from interference with non-union men. The C bin Coal & Coke Company had not joined the Oper

ors' Association, so it, also, made its own agreement with the union. Likewise the Canadian American Coal & Coke Company (now the Canadian Coal Consolidated, Limited), of Frank, Alberta, made a separate agreement, and, too, the Tabor district, east of Lethbridge, met the requirements of the U.M.W.A. It will be here mentioned that the Crow's Nest Pass Coal, Corbin, and Canadian Coal Consolidated companies are now included in the Western Coal Operators' Association, so that all the companies producing coal and coke in southeastern British Columbia and all the larger producers in Alberta (the total production in Alberta in 1910 was 3,036,000 tons, of which 2,800,000 tons is stated to have been produced by companies in the Operators' Association) are acting together against what they regard as the unreasonable demands made by the United Mine Workers of America.

President Lewis Appealed to.

Following the strike of April 1, 1909, at the mines represented by the Operators' Association, the operators appealed to Mr. T. L. Lewis, international president of the U.M.W.A., in Indianapolis, Indiana, U.S.A., to compel the members of the organization to carry out the Macleod agreement, which it was claimed had been practically accepted by the locals of the U.M.W.A. A representative of the president was dispatched to Canada, and negotiations looking to a settlement of the dispute and a resumption of operations, for which the miners were known to be anxious, were commenced, but the operators declining to give way, union representatives applied to the Labour Department, Ottawa, for a Board of Conciliation and Investigation under the Industrial Disputes Investigation Act, 1907, which was granted. In the application for the Board of Investigation it was asked that, among others, the following clause be included in a new agreement: "The company will require each person employed by them, or to be employed by them, as a miner, mine labourer, or otherwise, in or about the mines and coke ovens of the respective companies, to sign this agreement, as a condition precedent to continued employment of the person already employed or to be employed. The agreement to be placed in a book together with a legal check-off clause and signed by all employees."

Strike Called Contrary to Act.

In their reply the operators said, in part:

"2. The applicants have caused the said strike to be declared at each of the said collieries named, and the Board should enquire into the dispute existing at each and all of said collieries.

"3. That the discontinuance of operations at the said collieries is the result of a strike ordered by the President and Secretary of District 18 of the United Mine Workers of America contrary to the provisions of the Industrial Disputes Investigation Act, 1907."

In the agreement the operators, in their reply, submitted should be adopted by the Board it was provided that:

"(f) No check-off clause or deductions should be allowed other than as provided for by the laws of the Province of Alberta and British Columbia."

Board of Investigation in 1909.

The Board of Conciliation and Investigation was granted. The operators were represented by Mr. Colin McLeod, of Macleod, Alberta; the miners by Mr. Frank H. Sherman, president of District No. 18, U.M.W.A. These having failed to jointly recommend a chairman, the Government appointed Rev. H. R. Grant, of Fernie, B.C., to that position. The Board was practically in continuous session from May 20 to June 16, during which period much evidence was taken. The chairman and Mr. Sherman eventually made a majority report. Mr. McLeod, in his minority report, said: "Having in mind the agreements which existed between the parties prior to April 1, 1909, and the Macleod agreement, which was approved of on a referendum vote, I have compiled an agreement based on these agreements, which I would recommend to the parties for acceptance," etc. Regarding a check-off clause, Mr. McLeod said: "The applicants are undoubtedly entitled to a check-off clause in their agreement, but the check-off clause submitted by them being inconsistent with the laws in force in British Columbia and Alberta, should not be accepted, and the check-off clause of the old agreements should be continued, the same being shown in the proposed agreement submitted herewith." The "Check-off" and "Discrimination" clauses proposed by Mr. McLeod were as under:

"Check-off—The company will give to the United Mine Workers of America full recognition and concede the check-off system, that is to say, upon the individual request in writing of any of the company's employees, the company shall deduct such moneys from their wages each month as is designated for dues, assessments, fines, and initiation fees, in other words, the company will retain from the wages due employees any sums they may have given orders upon the company for in writing payable to such officers of the United Mine Workers of America as may be designated in such orders.

"Discrimination—No person shall be refused employment or in any way discriminated against on account of membership in labour organizations, and there shall be no discrimination against any employee who is not a member of a labour organization by members of such an organization."

Findings of Board Not Accepted.

The report of the Board was not accepted by the miners, so the mines represented by the members of the Operators' Association remained idle for three months, during which period neither side yielded. Eventually the officers of District No. 18, U.M.W.A., desisted for the time in their endeavours to secure "closed shop" and the concession of the check-off system as demanded by them earlier, so on June 30 an agreement was signed by the Operators' Association and District No. 18, U.M.W.A. The official Labour Gazette mentioned that this agreement "is practically the same as the findings of the Board of Conciliation and Investigation."

The position when operations were resumed in the summer of 1909, therefore, was, that the U.M.W.A. had by then succeeded in getting "closed shop" and the "check-off system" at the three collieries and the coke ovens of the Crow's Nest Pass Coal Company, the Corbin Company's mine, and the Canadian-American Company's mine at Frank, while the mines represented by the Western Coal Operators' Association, beside not having conceded either of these, had in their agreement a "discrimination clause" similar to that above quoted.

The Union's "Check-off" Clause.

In the agreement between the Crow's Nest Pass Coal Company, Limited, and its employees, as represented by District 18, United Mine Workers of America, the term of which agreement began April 1, 1909, and ex-

pired March 31, 1911, the following clauses were contained:

"The company will require each person employed by it, or to be employed by it, as a miner, mine labourer, or otherwise, in and about the mines and coke ovens of the said company, to sign this agreement, as a condition precedent to continued employment of the person already employed or to be employed."

"Check-off System—The company will give to the United Mine Workers of America full recognition and concede the check-off system; that is to say, upon the individual request in writing of any of the company's employees the company shall deduct such monies from their wages as is designated, for dues, assessments, fines, and initiation fees; in other words, the company shall retain from the wages due employees any sum they may have given orders upon the company for in writing, payable to such officers of the United Mine Workers of America, as may be designated in such orders, which shall be continuous orders, not revokable while the makers remain in the employ of the company; except that the employees embraced in the article headed 'Employees not under Jurisdiction,' may revoke orders as above given by them."

Operators' Association Now Stronger.

The Crow's Nest Pass Coal Company, the Corbin Coal & Coke Company, and the Canadian Consolidated Coal Company (formerly the Canadian-American Coal & Coke Company) having joined the Operators' Association, and there not being any company in a position to make a large production of coal and operating between Lethbridge and the western boundary of the Crow's Nest district (the McGillivray Creek Company, with a new mine near Coleman, Alberta, is stated to have an output capacity of about 300 tons of coal a day; it has not joined the Operators' Association), the operators along the Crow's Nest Railway west of Lethbridge, and those on the main line of the C.P.R., are acting together, so the United Mine Workers of America have not the advantage this time of lack of practically complete organization among the operators as they had in 1909. On the other hand, the U.M.W.A. is also stronger now than two years ago, for it now has in its 25 local unions a membership of 5,827, nearly all in the affected districts.

Men Affected and Coal Tonnage.

The number of miners affected by the present difficulty has been variously stated in recently published press despatches at a minimum of 7,000 and a maximum of 15,000. The latter is certainly a grossly exaggerated estimate, although if the strike be continued over several months, so as to necessitate the cessation of work at copper mines and smelteries and the taking off of freight trains, it is not unlikely the larger number of other men would be affected, directly and indirectly. In the summer of 1909 the number affected was stated at 2,100 directly and 10,000 indirectly; if the number of men employed at that time by companies not then included in the Operators' Association be added, the total of those directly affected would have been between 4,000 and 4,500. The average number of men employed in 1910 at British Columbia mines and coke ovens in the Crow's Nest district was approximately 3,100; the gross tonnage of coal produced was 1,529,000 short tons. No corresponding official figures are available for Alberta, but since it has been stated in press despatches that the mines in that province affected by the labour trouble produced 2,800,000 tons of coal last year, it may be regarded as quite probable the number of men employed in and about those mines was in excess of 4,000. So it would appear that not less than 7,000 men will be directly concerned, and, too, it may be conceded that, since there are 5,800 members of the U.M.W.A. nearly all in the affected districts, fully three-fourths of the 7,000 are union men.

Far-Reaching Effects Probable.

The possible far-reaching effects of a prolonged struggle between the operators and the miners have already been suggested by a brief reference to the copper mines and smelteries and the railways, that haul their ore to the smelteries, and fuel and other supplies for both mines and reduction works. A cessation of work at the mines and smelteries of the Boundary and Trail Creek districts would be disastrous, not only to those directly engaged in connection with copper mining, but also to all classes of trade largely dependent upon the mining and smelting industries for their chief support.

Chief Points in Dispute.

The prospects for an early agreement do not appear to be encouraging. The representatives of the miners offered to leave preamble, check-off, and discrimination clauses as at present, that is, to proceed with conditions as they have been—namely, closed shop and an effective check-off system with several companies, and open shop and discrimination clause as before with others, but the operators would not agree to any clause at all binding even a few of their number practically to the closed shop, or to a check-off which would tend in that direction, nor would they grant the general advance of 5.55 per cent. in wages asked for, only in some cases, but not in those cases—pillars and timbering—in which the union claims the pay is totally inadequate. So a deadlock was reached, and the conference ended.

The union knows that the Industrial Disputes Investigation Act has in the past been openly broken and that with impunity, so the suggestion of the Minister of Labour that the law must be observed is not likely to be heeded for the reason that in the past it has not been enforced.

Two dredges with steel hulls, said to be the first of the kind built in the West, are being constructed in San Francisco for the Yukon Gold Dredging Company. The dimensions of each are: length, 93 feet; beam, 3 feet; depth, 8 feet. They will have a bucket capacity of about 15 cubic feet, and will be operated by electricity.

The Board of Trade of Nelson, B.C., which is the most important town in the Kootenay district, recently unanimously adopted the following resolution, a copy of which has been sent to the Provincial Secretary: "Resolved, that this Board of Trade bring the attention of the Provincial Government the requirement in this district of a Mining School; either as branch of the Mining School to be connected with the Provincial University about to be erected at the coast, or in connection with the Nelson High School, and would further draw the attention of the Provincial Government to the Mining School in connection with the High School at Sudbury, Ontario, which is supported by the Ontario Government, and request that the British Columbia Government have inquiries made as to the operation of the same; and would further urge the erection and operation of a similar school in Nelson."

Plan and Purposes of Experimental Coal Mine of the U. S. Bureau of Mines, near Bruceton, Penna.

By George S. Rice, Chief Engineer, Bureau of Mines.

The explosibility of coal dust in air having been successfully demonstrated in the 100-foot gallery of the United States Bureau of Mines at Pittsburg, and in the longer galleries at Lievin, France, and Altofts, England, the next step in the investigation of coal dust explosions by each of the experiment stations was to determine the exact conditions under which such explosions took place. When these conditions were understood, tests of various preventative measures could be undertaken with some degree of precision. Prevention, or at least, limitation of explosions in mines was, of course, the real objective of the stations.

The gallery at Lievin, a short length of which was erected in 1908, was gradually lengthened to a distance of 820 feet, and an increase to 1,600 feet is under contemplation. The gallery at Altofts, also erected in 1908, was about 950 feet long as originally laid out. In both these galleries the limitation of strength prevents safe loading with pure coal dust for more than a distance of 400 to 500 feet; on loading beyond this distance the galleries are sometimes ruptured. The managements of these stations have expressed the desirability of making tests of coal dust in longer and stronger galleries, since it is impossible to solve all the problems surrounding an explosive wave in the short distances now available; moreover, methods of limiting an explosion which were successful with a loading of coal dust for a length of 300 or 400 feet, would probably not be so with a longer loading or a larger explosion.

The Director of the Bureau of Mines, Dr. J. A. Holmes, and his technical staff, at any early date appreciated these unavoidable limitations of a surface gallery, hence desired to obtain an underground gallery or mine opening, which would not only enable the tests to be made on a larger scale than is possible in external galleries, but in which experiments could be made under actual mining conditions. In such an underground gallery there would be no restriction as to the extent and violence resulting from explosion experiments, provided a suitable location was secured. Moreover, the methods of limiting and preventing explosions, the real objective of all such investigative work, could be tried out under real mining conditions.

It was foreseen that the greatest difficulties in experimenting in an underground gallery would be:

(1) To obtain certain desired natural conditions.

(2) Having obtained those, to carry out and control the experiments in a scientific way, and be able to get complete records in the face of violent explosions.

After a long search a location for the experimental gallery, or mine, has been selected near Bruceton, Pa. From 2,500 to 3,000 feet of straight entry can be driven from the outcrop in the Pittsburg seam. In some of the mines operating in the seam, in the past, great explosions have occurred.

The entries will probably be either level or slightly rising, except for irregularities, so that there will be no serious problem of drainage. The entries enter from a steep sidehill and a cover of from 60 to 160 feet is obtained. The openings are well located with reference to explosion effects, as there are no houses in the vicinity, except those in connection with the plant. The mine is fairly close to a railroad (one-third mile), so that the coal dug in advancing the entries can be loaded on railroad cars. By damming a ravine close at hand, water can be obtained for a boiler plant and fire protection. Natural gas for experimental purposes and for use in a gas incline engine and fan engine is obtained from a pipe line which passes a few hundred feet from the mouth of the mine. Finally, the situation is near enough to Pittsburg to allow convenient movement of the engineers and physicists between the testing station there and the mine. The location of the mine is twelve miles southwest of Pittsburg on the Wheeling Division of the B. & O. R. R. The coal and necessary surface surrounding the mouth of the mine, has been obtained at a nominal rental from the Pittsburg Coal Company.

Progress and Development—After a long continued search for the best location, which would give the desired conditions, the present site was picked, and about the middle of December permission was obtained from the Secretary of the Interior and the Director to proceed with the laying out of the mine. The surveys already having been made, the outcrop was uncovered and two parallel entries with forty feet of pillar between them, were started. At the time of writing this description (March 16, 1911) these entries have been driven in under cover over 200 feet. The right hand one, which will be considered the main entry, was started in the lower part of the coal seam, taking the top of the limestone, which is 5 feet below the coal seam, as a floor. Between the limestone and the coal seam there was at this point a hard shale; the entry was excavated in this and in 3 feet of the lower part of the coal seam, leaving up for a roof about 2½ feet of the main seam.

After going in about 50 feet in this manner, the floor was gradually raised on an upgrade until the excavation was wholly in the coal seam and the draw slate above it. The so-called "draw slate" is a soft shale or clay which comes down immediately on mining the coal. Above it, as is generally the case in the Pittsburg seam in this district, there is 1½ to 2 feet of so-called "roof coal," which is generally of poor quality and interspersed with layers of shale.

The parallel entry, which will be called the air course, was driven wholly in the coal seam. It is not intended to use the mouth of this entry in explosion tests. For normal driving this air course will be the return, and ventilation will be obtained by a small fan driven by gas engine located at the top of a small upcast shaft near the mouth of the air course. This shaft will be offset from the air course about six feet.

There will be another entrance to this air course joining at about 150 feet from the mouth, and which will enter at an angle of about 55 degrees, on the opposite side from the main entry. At the mouth of this side approach there will be placed a short length of

EXPERIMENTAL MINE NEAR BRUCETON PA.

A - Exit of Main Entry

B Plan View of Exit

concrete gallery with explosion doors, and beyond that a round steel gallery 120 feet long, 20 feet of which will consist of removable sections that can be rolled out of the way when it is desired to isolate the 100-foot gallery. This part will then be identical with the 100-foot steel gallery at the Pittsburg station, with one exception, a branch off same a short distance from the inlet to which a large reversible fan will be connected. The object of having this steel gallery, which is 6 feet 4 inches diameter, separable from the r is so that experiments similar to those conducte Pittsburg can be made. The gallery at Pittsburg continuously occupied with the testing of explos that systematic testing of coal dust cannot be un taken in it. When the removable sections before tioned have been rolled to one side and a steel lowered in place to cover the connection into the course, experiments can be conducted in the isol

llery without interfering with operations in the mine.

Dust Tests in Mine—At the start it is intended that al dust explosions will be originated in the steel llery and the explosion will enter the air course rough the branch, pass up same to the last open osscut, through the latter into the main entry and t to the mouth of same. The crosscuts will be driven a circle tangent to the entries. This will require e 45-degree turn and one semicircular turn of the plosion wave, a condition which seems to cause no stacle in a real mine explosion, nor does it cause fficulty in the Altofts Gallery. The records of exriments in that gallery show that on the return side, at is, towards the exhaust fan, the dust, carried by e air current and the advance compression wave of e explosion, has been inflamed and the flame has ssed around a number or all of the five right-angled rns in that gallery.

The purpose of this method of initiating explosions i the outside gallery of the experimental mine is to oceed from the known conditions in the gallery (as veloped at the Pittsburg Gallery) to the unknown nditions prevailing in mine entries. There is also other object, that while entries are being driven it ll give double the length of travel for the explosive ve and thus allow the trying out of the mathemati- l instruments, before the final explosion experiments ich may be originated in the interior of the mine.

Fire Damp—Besides making investigations of the plosibility of coal dust in pure air, it is intended to ke tests with small percentages of methane in the . It is generally recognized that a very slight mount of methane, even as low as ½ per cent., may rease the chance of ignition of coal dust and more dely extend an explosion that has once been started.

The location of the experimental mine is fortunate having a natural gas pipe line near it. This line xes gas from some gas wells in the same ravine. It intended to take a branch from this gas main for e in a gas engine hoist and in a gas engine for driv- a small ventilating fan. It will also be used for e purpose above indicated, of introducing when deed small quantities of gas into the mine.

Natural gas has very nearly the same composition as e marsh gas of the coal seams, the difference being at in addition to the methane (CH_4) there is from to 15 per cent. of ethane (C_2H_6) This slightly ries the properties of the mixture of air for its combstion, but the difference for practical purposes is gligible.

The gas will be piped to certain points and by a stem of mixing with the ventilating current will be rried through in whatever proportions may be reired, approximate percentages will be determined rough meter measurements and precise determinans by sampling the air and gas mixture and analyzg. It is considered that this line of investigation of e effect of small percentages of methane is most imrtant, and the need for it has been expressed by forn critics of coal dust experimentation now carrd on.

Concrete Lining—It is anticipated that great explosive force will be developed at the mouth of the in gallery; hence it is intended that the timbering ich is now in place must be supported by reinforced ncrete walls and arching. The latter will present a ooth surface to the explosive wave and thus prevnt great falls at the mouth of the mine, the occrrence of which would lead to heavy expense and day in clearing up after each experiment.

It is the plan to concrete the approach leading from the steel gallery to the air course, and it may become necessary to concrete between this connection to the mouth of the air course, although it is not intended to load that portion of the air course with coal dust. It is expected that the explosion wave entering from the gallery entrance will not have gained sufficient momentum at the junction with the air course to break down doors or stoppings erected between that point and the mouth of the air course, but will be deflected into the air course toward the face.

Method of Driving Entries—The method of driving entries is the usual one employed in the Pittsburg coal seam. The coal is undercut and shot down with explosives, which in this case are of the "permissible" type, electrically fired. The coal is loaded on pit-cars, which are hauled by mules, to the mouth of the mine, thence over an outside tramway with slight descending grade, to the head of a rope incline. Trips of cars are lowered, by the hoist under brake, to a trestle and tipple located on a siding of the B. & O. R. R.

Buildings and Apparatus—It is necessary to have a considerable number of buildings; these are now under construction. There will be a boiler house with boiler to furnish steam for the several engines, including the fan engine. A crusher and grinder house will be necessary to grind up the dust for the experiments; as much as four tons will be necessary when the mine is fully developed. There will be a blacksmith shop containing small equipment for the necessary repairs and an engine house for the incline engine. There will be a combined office and observation room for observations and the starting of explosions, in connection with which there will be a small laboratory for field analyses of gas and mine air samples. Several small buildings, including a barn for the mules, have already been constructed.

Ventilating Fan—The ventilating fan for the experiments must be of such size as to create all the conditions which may surround an explosion in a mine. It is desirable to obtain high velocity in restricted areas, say, 1,500 feet per minute over a considerable distance. A capacity of 80,000 cubic feet per minute at a pressure of 2 inches water gauge and 15,000 cubic feet per minute at a pressure of 6 inches water gauge, is specified and has been guaranteed by the builders. The fan is made reversible, so that experiments may be conducted with dust explosions going against the air current as well as dust explosions going with the air current. The Altofts gallery fan is not reversible and the explosion portion of the gallery is at the intake end.

Pressure and Recording Instruments—The important objectives of the experiments are to obtain the speed of the explosion as indicated both by pressure and by flame; the variation in pressures at different points along the course of the explosion; the temperatures; and the samples of the gases immediately preceding the inflammation of the dust or gas and immediately following the inflammation at a given point. Such experiments will require apparatus of an extremely sensitive nature.

A similar set to those used in the Altofts gallery has been purchased from the Cambridge Scientific Instrument Company, of England. These were designed primarily for external galleries, but it is believed there will be no serious difficulty in arranging them in steel plate boxes sunk into the coal rib. It may be found necessary to design new and additional apparatus.

An important point in the use of the recording instruments is their driving, also the making and breaking of electric circuits. To connect these instruments with the outside will require the wiring to be done in such a way that it will not be torn out by the explosions. It is proposed to place the wiring in pipes placed in a groove in the coal rib and at the mouth of the mine; these pipes will be set in concrete but arranged with suitable boxes at short distances apart so that the wires may be gotten at.

It is evident to make the wires safe under the enormous pressures which are expected, which may run up several hundred pounds or more per square inch, will need great care. To obtain the currents for the instruments will require a very steady running generator engine set. It is expected to obtain a set which will be sufficiently large to allow some lighting with incandescent lamps in and around the mine.

Limiting or Preventing Explosions—The real importance of the experiments is not the mere study of explosion waves, although of great scientific interest, but to study methods for preventing or limiting explosions. It is, therefore, proposed to experiment with all the important methods that have been suggested up to date as described in U. S. G. S. Bulletin 425 and Bureau of Mines Circular No. 2, among which may be briefly recited, watering by water sprays, by exhaust steam sprays and by deliquescent salts (calcium chloride) and by rock and shale dust in various ways. It is believed these experiments tried out in a mine on a sufficiently large scale can effectually demonstrate the relative efficiency of the various methods.

Explosives—A secondary purpose of the experimental mine, and by no means an unimportant one, is the study of explosives which have been placed on the permissible list for use in gaseous and dusty coal mines—testing them under actual working conditions in coal.

Dust Production—Another purpose to which the experimental mine can be put is in studying the relative production of inflammable dust by different types of machines which undercut or shear the coal.

Gasoline Locomotives—Still another purpose is the testing out under mine conditions of gasoline motors to determine the safety of the apparatus in actual use and the degree to which the air may be vitiated by the exhaust gases.

Electrical Devices—It is probable that many electrical mining devices can be tried out under actual service, together with tests of insulation of wiring.

Concrete, also Steel Timbers and Props—The growing scarcity of mine timbers, as well as the danger of fire from their use, suggests the importance of testing reinforced concrete timbers and ties; also steel props and ties in the experimental mine.

The relative advantages of brick arching and reinforced concrete for lining the main entries can also be studied, and under severe conditions.

It is probable that the equipment will be sufficiently installed by the first of May to try some preliminary experiments. In the meantime the entries are being driven as fast as possible.

The next general meeting of the Western Branch of the Canadian Mining Institute is to be held at Trail, B.C., on or about May 18. As the headquarters in British Columbia of the Consolidated Mining & Smelting Company of Canada, Limited, owning the large smelting works and refinery in operation there, are at Trail, it is expected there will be a good attendance of members and an interesting meeting.

Pit Bottom Arrangements for Large Outputs.

(Written for the CANADIAN MINING JOURNAL by W. A. Clifford.)

The sketch plan of mine herewith was prepared for the discussion of a paper contributed by Mr. E. H. Fohl, consulting engineer of Pittsburg, to the Mining Institute of America, at its December, 1 meeting in the Carnegie Technical School. The of the paper was "Shaft Bottoms." Particular r ence was made to the manner of distributing the from that point, and especially to protecting the working at the pit's eye in severely cold weather.

Mr. Fohl advocated the use of undercasts for crossing, but the writer is not clear whether he posed to drive them in natural strata underlying coal.

The subject is one of great practical importanc coal operators and mining engineers, in view of fact that at no very remote date deep mining wil volve costly installations, and therefore the win of extensive areas from a single plant, with large put to insure financial success.

In his endeavours to obtain sketch plans of s bottoms where large outputs are obtained, the w was not successful; therefore, as a forlorn hope an endeavour to atone for his failure, he hurri prepared a sketch plan to illustrate what he ha say at the meeting, and at the request of the Ed of the Institute, now put his remarks in a less sultory form than when uttered verbally.

In these days of fierce blasts, where the roadw of a mine have to bear strains akin to those pres the walls of a great gun barrel during firing, the o cast has been found to be the weak point. Carb oxide poisoning, rather than burning, has now co quently become the chief contributor to the gre increased death roll in colliery explosions. Overh air crossings of the most substantial construction h been destroyed, like a house of cards, thick wall reinforced concrete proving altogether inadequat resist the force of such explosions as have occur where coal dust played the most active part.

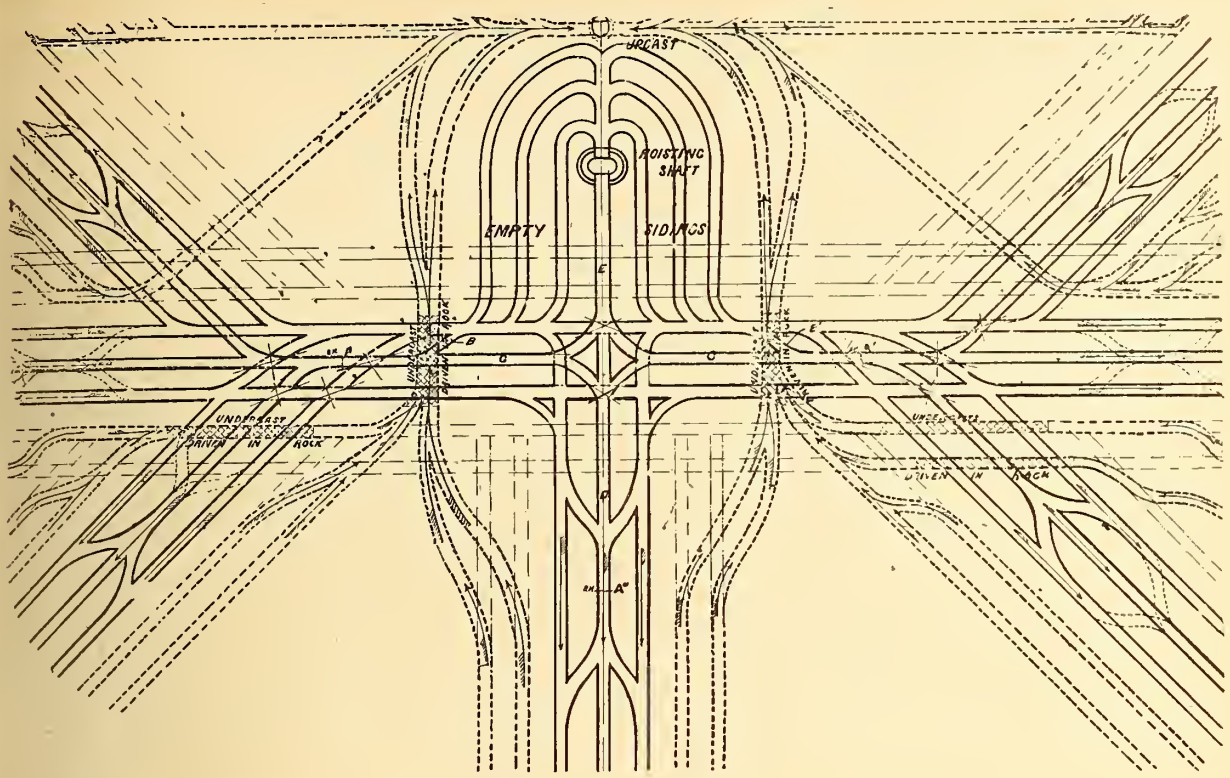
The writer agrees entirely with Mr. Fohl, that best and safest form of crossing for a fiery min the undercast, and he would hardly limit this to w floor conditions and drainage admit its use, but w rather add that it is worth while to provide aga adverse conditions to gain the advantages offered air crossings driven in the solid under the floor.

Two systems of that form are known, and h their advocates among the leading mining author in Europe.

The first consists of driving the channel conve one air current across another, through the s strata overlying the coal, beginning at the floor l and gradually rising to a crown or summit dire over the road to be crossed, then by descendin similar grade to the one it rose by, until the coal f is reached or "footed" on the other side.

The other system proceeds by passing down gr to a point directly below the road to be crossed, t rising on the other side until another point or airwa is reached, level with the roof and floor of the coal.

The first system has been used in a few mines, du the last half century.



The second system has been applied in a very limited number of cases, where the conditions of floor, pitch, and drainage, appear naturally to invite its adoption, and perhaps it might be added where mining practice was specially resourceful and intelligent.

The British Government in the Mines Regulation Act of 1862, fixed 10 feet as the thickness of natural strata between the upcast and downcast shaft. This was calculated to resist any blast that could obtain with the average ventilation of that day, but the writer would be inclined to fix the distance between the floor of an air crossing drift and the roof of the road it crosses, at something greater than 10 feet, depending much upon the strength of the interlying rock.

Both the overcast, and the road it crosses should be lined with masonry at, and a little distance beyond, each side of the crossing. With an air crossing below the coal, the undercast road only need be lined with masonry. The overlying road acts as a natural relieving arch to the crown and haunches of the lower one, by carrying most of the pressure of the superincumbent strata. This allows a thinner division between the two roads, and consequently a smaller bending of the air current, a matter of some consequence where the initial volume, or a primary split is involved.

In the outline plan shown, a large output is contemplated, and the coal is hauled from the working places to a number of bank-heads or summits. formed by raising the roads at the summits, and by grading each way, or by lowering the hoisting shafts bottom and cutting away the floor to the several bank-heads. The grade from the bank-heads to the shaft should be even and about 2½ per cent.

The choice of methods of forming these bank-heads, or summits, must be carefully considered. In the former case mentioned, raising the road by material shot down from the roof, the bank-heads will be approached from the workings by a gradient, necessarily either steep or long, or against the load. In the latter case, lowering the landing at the shaft and cutting away the floor to grade, the lift at the pit bottom, hereafter described, must be higher, which is undesirable—15 to 20 feet should be the limit. Good judgment would look at the problem as presented in the particular case, and probably strike a compromise by blowing down some top, and blowing up some floor, the disposal of the dirt being taken into account; but the efficiency of the job, will be the paramount consideration. Taking up some floor in the empty sidings and adjacent engine roads, should be carefully considered. The greatest efficiency, the smallest prospect of repairs, and the smallest first cost, will always be kept in sight. The kick-back switch shown in Mr. Fohl's sketch and followed by the writer, in the one presented to the Institute along with his talk, has been changed to that now shown to meet the contemplated larger output, which further thought suggested.

The kick-back arrangement involves the risk of stopping the whole pit, which is too serious a matter, especially with a large output Empty roads curving towards the main haulage roads as shown in sketch, are not new. They were employed by one of our past presidents, Mr. F. A. Schellenberg, at the Westmoreland shaft 40 years ago, and the writer knew modifications of them in the north of England and Midlands as long ago as 1867.

The operation of the plan described herein, and shown graphically in the sketch, is very simple. The coal is hauled from the workings by locomotives over the bankheads, or delivery points, each of which points is identified with a particular producing section of the mine. In operation the locomotive having hauled its train over the summit, drops down a steep shunt, B or BI, to the back road and thence to the empty siding.

Thus released from the control of the locomotive in front of them, the waggons commence their unaided journey down the incline towards the shaft, as fast as those in front of them move on, impelled by the same power of gravitation, until they ultimately reach

their goal, and are in their turn hoisted to the surface, making way for those behind them, which are subsequently hauled over the same bankhead.

The empty locomotive having dropped down the shunt and made its way to the empty sidings, has taken and delivered another empty train inbye, in exchange for a full one, and is now pulsating its way to its bankhead to deliver it. The process goes on repeating itself. From every district of the mine trains are being hauled over the bank-heads with the most perfect regularity and alacrity that efficient equipment and close supervision can induce during working hours.

Several district roads feed into central arterial ones, CC, which in plan shown range in straight lines, longitudinally towards the boundary of the coal to be worked. These two, and perhaps another one, D, at right angles to them, deliver their coal into the wide arched pit porch, E, of considerable length, with four tracks laid in a line with those on the cages. There are opposite each cage controlling devices to automatically or otherwise release, as the cage strikes the bottom, just as many waggons as the plant is designed to pull at one time, and no more. The full waggons by gravitation assisted by power, or by power alone, push the empties from the cage to the platform of an elevator at the back of the shaft, and the same movement automatically raises stops, which hold the waggons in a fixed position upon the elevator platform. During the time a hoist is being made to the surface, the elevator platform, which slopes in the direction the empties must travel when released, is raised to the landing. The stops which secure the waggons on the platform are automatically dropped, as soon as the landing is reached, by mechanism which cannot operate sooner. The waggons run out on the rails of the empty roads and gravitate to the proper point where the locomotive can reach them and haul them into the workings to be refilled.

Over the entrance to the empty porch or mouthing, a man or boy sits to operate the lift, and by means of switch levers at his side to distribute the waggons as they are lifted. To enable him effectually to perform these duties, he occupies an elevated seat or platform, from which he can see all that goes on in the shaft bottom on the one hand, and the landing and travelling of the empty waggons on the other hand.

It will be apparent that the purpose of providing the somewhat extensive empty sidings on each side of the pit, is to keep up the supply of empties in the case of any temporary hitch in winding, or stoppage at the top, where the large standage of full waggons between the bank-heads and shaft provide for continuing hoisting when the supply of coal from the hauling roads is from any temporary cause curtailed or stopped. For a mine hoisting 1,200 an hour, the writer conceives that a standage of 350 to 400 empty cars is not too much.

The operator at the lift can divert cars to either side whenever the demand calls for it. And that he may know just how many cars are standing, simple electrical devices, with illuminated dials, at the entrance to each switch road, may be contrived without any serious stretch of ingenuity as nothing requiring any mental application should be allowed to distract the attention of a man engaged in such a strenuous occupation.

To prevent the smashing of waggons turned down grade at the switches, when they come in contact with those already standing in the empty road, artificial retardation must be resorted to, the simplest form of which is undulations of grade in the empty road designed for the purpose.

The details of this paper and the drawing are not claimed to be new. Some portions of them will be found in the arrangement in nearly every modern colliery. The writer has brought these scattered elements of good practice together, and incorporated them in a fairly complete scheme, by what may be termed a process of mechanical synthesis.

It is for practical men who peruse this description to assimilate what they consider good, and reject what they may deem not good.

The writer, however, feels the utmost confidence that, as an engineer, he could carry the scheme into practice without serious modifications, and also without any abridgement of capacity.

The sketch as drawn is too much crowded—the pillars thin—and hence it does not represent what would be good practice in actual construction. This condensation has been done to get the sketch into small space and in no way affects the principle of operation of the scheme.

Safely and effectually to work such a mine as projected above, one mainshaft of good size or two small main shafts, would be required. The structure of these shafts or shaft should be such that an explosion could not render them useless.

As will be seen, the plan contemplates the complete separation of the intakes from the returns, except those parts of the mine where coal is being worked. And as fast as a working is finished, a substantial air-tight stopping should be put in at each end of the pillar pierced with tamped stowing between them, in order to restore the wall separating the intakes from the returns, to as near as possible the original strength of the coal pillar.

Fresh air laid on to pass principally along the two outside roads, in each set, the middle road being a hauling road, up to points not shown, just behind the several bank-heads, the two outside roads being in consequence of this arrangement, ordinarily free from dust. The air in the middle road to be scaled to more than the sanitary requirements of the men working in it, so that in case of an ignition of the dust, the flame will have a chance to die out for want of oxygen, instead of vigorously travelling inbye, and wrecking the shaft, as now usually happens.

In case of longwall working the pit pillar would require to be of very ample size.

Hon. Wm. Templeman, M.P., Dominion Minister of Mines, is stated to have promised the Board of Trade at Chilliwack, B.C., that Mr. Charles Camsell, of the Geological Survey, who spent the field-work season of the last four years in the Similkameen and Nicola districts of British Columbia, will make a reconnaissance survey of the Steamboat Mountain promising mining field, which has come into prominence in the coast cities of British Columbia during the past year. The new field is in Yale district, and has thus far been reached chiefly by way of Hope, on the Fraser River. Provincial Government parties will, it is expected, make trails in from Chilliwack, on the west, and Princeton, Similkameen, on the east of the Hope Monntains, which, if done. will open a second and third route to Steamboat Mountain region. As yet not much development work has been done, but many mineral claims have been staked, and assay returns from mineral specimens from some of the claims encourage the hope that much gold-bearing ore will be found there.

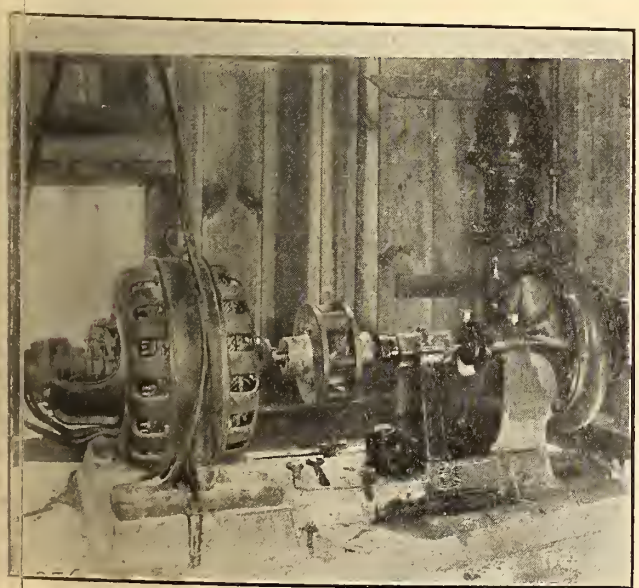
Electric Pump Replaces Steam Pump in Stone Quarry.

The view of the quarry shows the steam engine partly dismantled and left to rust out its days in the weather, also the shanty in which the new pump is installed and the suction and delivery pipes. The view inside the shanty shows the motor and the pump, installed across the end of the shanty close to the suction

and delivery pipes. As the motor is about 2½ feet high an idea may be had of the relative sizes.

This outfit, consisting of a No. 6 high duty American centrifugal pump driven by a 30 h.p. Westinghouse alternating current motor running at 690 r.p.m., was installed over a year ago by the Kankakee Electric Light Company, in the stone quarry of McLaughlin & Master, Kankakee, Ill., to keep the quarry dry, and has been giving excellent service ever since.

The pump delivers 1,100 gallons per minute against a discharge head of 55 feet and a maximum suction of 25 feet pumping the water from the quarry sump. The water is started and stopped by a ball float and master switch in the pump house and a magnetic starter on the bank above the quarry. The pump works automatically, running eight hours out of the twenty-four; that is, the sump fills in one hour, and the pump empties it in a half-hour.



The owners of the quarry were somewhat skeptical of the powers of the pump when it first appeared on the scene and called it a "toy," and it did look diminutive beside the steam pump. When the pump was connected and ready to work they came around confidently expecting that this new device would be totally inadequate and that the firm was going to "get in wrong." But when the equipment dug right into the load and pumped water in a large stream and never once hesitated until the sump was emptied, their surprise and speedily their pleasure was great. So pleased were they that in 24 hours after the pump began work orders were given for the complete abandonment of the steam equipment.

The motor application is a particularly good one. The first point of excellence is the use of a flexible coupling between the pump and the motor, which permits slight inaccuracies in the alignment of the two shafts. Some form of flexible coupling should preferably be used on all installations where the motor is direct connected to any two-bearing machine. The second point is the excellent concrete foundation provided even though the pump and motor are mounted on the same cast iron bed plate

SHEEP CREEK GOLD MINING CAMP, B.C.

Mr. W. M. Brewer, of Victoria, B.C., recently stated, for publication, that he considered Sheep Creek, in Nelson mining division of the West Kootenay district, the best camp he had seen in British Columbia.

"I consider it the best camp," he said, "for the reason that the Nugget ground is 6,000 feet above the sea and the Queen 2,000 feet below, with the Mother Lode workings 500 feet deeper than the Nugget—that all are in the same geology, though there is no relation between the veins of the various properties.

"On the Nugget there are oxidized gold-bearing ores on the surface and in the workings, 400 feet below they are still getting the same kind of ore. From it fully 80 per cent. of the value can be saved by amalgamating. In the Mother Lode, while a large proportion of the ore is free-milling it becomes more of a sulphide. The Queen is 200 feet below the level of Sheep Creek and here the ore is thoroughly sulphide, but they claim that there is in it sufficient free-milling quartz to save about 60 per cent. of the value on the plates.

"All of the development on the Nugget and the Queen has been paid for out of the bullion received from the mills on the properties—a 4-stamp mill on the Nugget and one of 20 stamps on the Queen. The Nugget is owned by a company, the stock of which is largely held in Vancouver. The Mother Lode has been developed by outside capital and is now arranging to put in a mill.

"In addition to these properties there are the Kootenay Belle group, the Clyde, and Fawn groups, all located in the same geological formation made up of alternating belts of schist and quartzite with some dikes of igneous rocks as intrusives. The general trend of the veins is easterly, while that of the country rock is northeasterly. In all these the fact that the veins are true fissures, cutting through the quartzite diagonally, is very noticeable. In value saved, they vary from $12 to $25 per ton on the mill runs. What is the extent of the area of the camp? That is problematical. Whether there will be any mines of value found outside the quartzite and schist zone remains to be proved."

Outlook for Placer Gold Mining in British Columbia.

By E. Jacobs.

The preliminary estimate of the mineral production of British Columbia in 1910, published by the Provincial Bureau of Mines in the first week of this year, shows a small increase in the value of placer gold as compared with 1909. The production in the latter year was the smallest during a fifteen-year period—1895-1909—both years inclusive. The officially recorded value of production in these years, respectively, was $477,000 in 1909, and $481,683 in 1895. There were, however, several earlier years in which production was still smaller, as follows: In 1891, $429,811; 1892, $399,526; 1893, $356,131; and 1894, $405,516. That for 1893 was the lowest on official record, the statistics commencing with 1858, which year was credited with an output valued at $705,000. Thereafter, for twenty-three years—1859-1881—the yearly production was always in excess of $1,000,000, with that of 1863 ($,913,563) as a maximum, and of 1880 ($1,013,827) as a minimum. Since the discovery, in 1898, of the Atlin placer gold field, there have been five years in which the output was in excess of $1,000,000, with that for 1899 ($1,344,900) as the highest. The avxerage yearly production for twenty-five years, 1858-1882, was $2,$25,986, with an aggregate for that period of $50,649,656; that for the next twenty-five year period, 1883-1907, was only $755,978, and the aggregate $18,899,447. The addition of $1,606,000 for the last three years, 1908-1910, will show the aggregate value of the production of placer gold during all years to 1911, namely, $71,155,103.

It will be seen, then, as compared with the past, the production of placer gold in quite recent years has been small in this province. There is, though, good reason to look for an increase this year, and, given a fairly large water supply, also during a number of years to follow. A heavy snowfall in Cariboo district during the winter now closing warrants expectation that there will be plenty of water for the ensuing season's gravel-washing. In addition, larger and more productive hydraulicking operations are expected in the Quesnel mining division of Cariboo than for several recent years, for it is probable the water-supply system of the Quesnelle Hydraulic Gold Mining Company will be sufficiently advanced towards completion to admit of hydraulicking being commenced about the middle of next summer, and being continued during fully three months thereafter. If this expectation be realized, there is likely to be at least $100,000 recovered by that company before the season shall close, for it expects to operate under conditions that will be more than usually favourable, owing to physical advantages connected with its water-supply system and the lay of its gold-bearing gravel beds. In the Cariboo mining division, too, the outlook is regarded as being decidedly promising, for Mr. John Hopp's several placer mines about Barkerville have been provided with facilities for a larger water supply and equipped with additional hydraulicking appliances, with the object of moving a larger quantity of gravel, and recovering more gold than in past years. In this division there are, as well, several hydraulic enterprises equipped for working on a smaller scale, the combined production of which will contribute an appreciably large amount to the total recovery of gold in this district.

Conditions in the Atlin field are also promising an increased yield of gold, although the North Columbia Gold Mining Company, now the largest producer in this district, was able to operate to a large capacity last season, with a correspondingly enlarged production as compared with that for 1909. Several other operators may be expected to add considerably to the total for this field, though not to a similar extent as the North Columbia Company, which possesses an abundant supply of water, and has large areas of gold-bearing gravel favourably situated for being quickly moved.

There also appears to be a prospect of an increased recovery of placer gold in East Kootenay next season than for some years past, preparations having been made last season to operate a hydraulicking plant on Perry Creek, in Fort Steele mining division. To allow of the gravel being moved more quickly, a steam shovel has been put in, and other arrangements have been made to carry out the undertaking on a scale that will facilitate the recovery of sufficient gold to make the enterprise a profitable one.

With much attention being given to the country now being rendered more accessible by the construction of the Grand Trunk Pacific Railway through central British Columbia, it is not too much to expect that there will be done more prospecting for placer gold along some of the many streams considered likely to be found auriferous, but these are uncertain prospects as compared with those previously mentioned in connection with the Cariboo, Atlin, and East Kootenay districts. The last are of themselves sufficiently promising to justify the opinion that the production of placer gold will, at any rate for several years, show a steady increase and will attain to larger proportions than the average of the last three years.

Missouri Zinc

Canadian readers of the Journal, especially those connected with the zinc and lead industry, will be interested in the following tables reproduced from the annual mining edition of the Joplin Daily Globe:

All the zinc blende in the Joplin district is purchased on a base price per ton of concentrates running 60 per cent. zinc contents. A penalty of $1 per ton is imposed for every per cent. that the concentrates fall below this base in zinc tenor, and a corresponding bounty is allowed for each per cent. above 60. A similar penalty is added for iron contents and all settlements are made on dry weights.

The prices of zinc blende for 1910 fluctuated from $46 base in January to $40 in March, $36 in April, and in August, ore sold as low as $35, with a steady advance to $48 in November, and the year closed with a gradual decline. The lead market suffered in the same manner. In 1907 lead concentrates sold as high as $88 and $90 per ton, whereas the average for 1910 was in the neighbourhood of $52.

The imports of zinc ore for 1910, according to the United States Bureau of Statistics, amounted, all told, to 72,854 short tons, with a metal content of 25,82 tons, equivalent to a 36 per cent. average metal content.

With the exception of 1907 this metal content is the largest ever imported and the ore tonnage is the largest ever imported with the exception of 1909 and 19.

The importation of spelter shows a decrease of

cent., notwithstanding a reduction in duty from to 1⅜ cents per pound.

The following table, compiled by the United States Geological Survey, gives the imports of zinc ores from Canada and Mexico since the year 1904, in tons of 2,000 pounds:

	Calamine. (free).	All other (dutiable).	Total
1904			
Canada	.....	.....	.....
Mexico	.....	2,264	2,264
Total	.....	2,264	2,264

1910.			
Canada	.....	4,927	4,927
Mexico	.....	67,927	67,927
Total	.....	72,854	72,854

Chili exported to the United States in 1910 over 13,000 tons of zinc ore containing a little over 13 per cent. zinc, but the zinc content was lost in the process of smelting for lead.

These figures show that Canada's proportion of the zinc imports is very small. On the other hand, the Canadian ores were of a much higher grade than those imported from Mexico.

The following table shows the production and value of the zinc and lead ores from the various camps in the Joplin district:

DISTRICT'S RECORD ORE PRODUCTION.

The Output in Pounds and Amount Paid for Lead and Zinc Ore by Camps.

Camps.	—BLENDE— Pounds.	Value.	—CALAMINE— Pounds.	Value.	— —LEAD— Pounds.	Value	Total Values

British Columbia is the largest producer of zinc ores in Canada, and the bush fires in the vicinity of the zinc mines account for the large decrease in the zinc ore exports to the United States. The railway used for transporting the major portion of the tonnage was entirely destroyed for a distance of several miles.

"Comparing the Canadian imports of 1910 with 1909 and 1908, it will be noted that they fell off over 50 per cent., when in reality the mines have increased their productiveness and may be expected as heavy importers as soon as the transportation can be replaced. More attention has been given zinc production in British Columbia the past year than any year since 1907, and the whole province has entered into the work of making the mines producing zinc, profitable, and to that end have been securing the aid of the Dominion Government in the experiments on electric smelting, so that the ores of that country can be smelted at home and thus escape the loss occasioned by the high freight rates and tariff to American zinc smelters."

This statement by the mining editor of the Joplin Globe, who is an accepted authority on the Joplin district, shows that the zinc smelters of the United States are thoroughly conversant with conditions in Canada. If the smelters of the Oklahoma and Kansas districts can make a profit importing our high grade ores, in the face of the high duty and almost prohibitive freight rates, surely there is an excellent opportunity for a centrally located smelter, where the Canadian ores could be reduced to spelter, and then exported to the United States if the Canadian product could not compete successfully in the open markets of the world.

Portland Canal Mining Company

The directors of the Portland Canal Mining Company, Limited, have received from Mr. W. J. Elmendorf, manager of the company, the following communication, under date March 21·

"The proposed addition to the concentrating plant of the Portland Canal Mining Company is for the sole purpose of handling more ore at a decreased cost per ton and thereby assuring larger profits, not only in the aggregate, but per ton of ore treated. Furthermore, it is exactly along the lines contemplated by the management from the beginning of the mill construction. No new devices are to be employed, and none of those now in the mill, and used in the very satisfactory run of last fall, are to be discarded

"The plants of concentrating machines, as installed, consists of four jigs, handling 5, 3, 2 and 1 mm. feeds; one Wilfley table and one Overstrom table, for the finer sands; and two vanners for the slimes. Experience showed that while all the machines used were satisfactory, the Wilfley table was pre-eminently so. Not only did it most successfully handle its own size of feed but, on this particular ore, it was equally efficient on sizes up to 2 mm. This was determined by diverting No. 3 and No. 4 jig feeds on to it. Moreover, it showed a capacity almost equal to a jig of these sizes. At the coarser sizes, 5 and 3 mm., the capacity of jigs greatly increases and it is for this and other reasons advisable in any concentrating mill to treat as much ore in a coarse condition as is feasible.

"The proposed plan of changing the 2 and 1 mm. jigs to 5 and 3 mm., thus giving two No. 5 and two No. 3 jigs, at least doubles the jig capacity. In order to handle the increased 2 and 1 mm. feeds to keep pace with this increase, six more Wilfley tables should be provided. The Wilfley and Overstrom tables now in the mill, and the vanners, will be used on the fi ores. In order to be sure to meet the increase in co centrating facilities with crushing capacity, it is al proposed to provide a larger crusher. Our prese one will be used later, when a further increase in t mill is warranted, as the orebodies in the mine a developed.

"The purchase of these machines and their nec sary connections, and a simple piece of constructi involving no foundation work, but merely the exte sion or enlargement of our concentrating floor, a other minor changes, cover the proposed additio These will cost about $15,000, and will give more th 75 tons daily capacity.

"Unless some most unreasonable delay occurs, t plant should be complete and running within 90 da from date, if the machinery is ordered at once."

The additional machinery recommended by Mr. El endorf has been ordered, so that the larger outp from the mill, as indicated in the foregoing commu cation, may be expected to be made after about t middle of next summer.

Slow Progress on Zinc Problem.

The Liberal Association, Nelson, B.C., has receiv the following letter from Hon. William Templema Dominion Minister of Mines:

"I have your letter of Feb. 8, inquiring for inform tion concerning experiments that are being conduct by the Government in connection with the reduction zinc ores.

"I may say with regard to this matter that the d partment has secured the co-operation of Dr. Ingal the well known mining engineer of New York, who now devoting his attention to this problem.

"Dr. Ingalls has investigated various proposals th have been made in technical literature and expe mental practice for the treatment of zinciferous or but he does not think that any of the proposals so f submitted would afford any solution to the proble He is also in touch with people in America and abro who are working on problems of a similar charact

"While none of this work seems to be directly a plicable to the conditions of British Columbia, some it contains the germs of what may be useful ide The experimental work done by the Canada Zinc C at Vancouver and Nelson has been thoroughly r viewed. The manager of that company courteous placed the plant at Nelson at the department's disp al, but Dr. Ingalls did not deem it advisable to und take experiments upon a large scale anywhere un certain fundamental conditions had been determin upon a small scale.

"Certain plans of experimentalization have be formulated, which include electric smelting. T metallurgical laboratory at McGill University is bei used for these experiments, Dr. Alfred Stansfield, the university, an experienced electro-metallurgical e perimenter, having immediate supervision over t work.

"Experiments with the British Columbia ores b gan during November, and are now in progress. It too early yet to forecast what the result will be, b Dr. Ingalls states that the tests have afforded valuab information respecting conditions affecting the desi of electrical furnaces for zinc smelting.

"Experimental work in new fields, involving the designing and construction of apparatus, is necessarily slow, and particularly so in the case of a metal possessing the peculiar properties of zinc.

"It is proposed to carry on the experimental work on a large scale in British Columbia, as soon as the preliminary work has indicated some advisable way."

Personal

Managers of hydraulic placer gold mines in British Columbia who have spent the winter away from the districts in which their respective mines are situated, are returning to prepare for the expected early opening of the hydraulicking season. Among them are Mr. John Hopp, of Seattle, Washington. whose mines are in the Barkerville district, Cariboo; Mr. John B. Hobson, of Victoria, B.C., who is opening a new mine near Quesnel Forks; Mr. Howard W. DuBois, of Philadelphia, Pa., who is in charge of the construction of a 17½-mile ditch in Quesnel mining division for the Quesnelle Hydraulic Gold Mining Company; Mr. J. M. Ruffner, of Cincinnati, Ohio, president of the North Columbia Gold Mining Company, which last season recovered about $150,000 worth of gold from its placer mines in Atlin district, B.C., and others. There was a heavy fall of snow last winter in the chief placer mining districts of British Columbia—Cariboo and Atlin—and a long and profitable season is expected to result from the consequent large supply of water for mining operations.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Safety Lamps.

Apropos of the fact that the Government of Nova Scotia is about to make safety lamps compulsory in all the coal mines of the Province, it is interesting to note that the centre of controversy in England has shifted from the question of the merits of safety lamps as compared with naked lights for mines, to the question of whether some so-called "safety" lamps are really what their name implies. The necessity of having nothing but closed lights is not now the subject of argument, and is taken for granted. It is, however, pointed out that there is a great and unnecessary variety of safety lamps, some of them containing more or less objectionable features which have been brought into prominence by recent disastrous explosions. It is now proposed that safety lamps shall be submitted to a series of rigid tests in explosive mixtures under varying pressures and velocities of air, and that only those lamps which prove themselves safe under such conditions shall be permissible for use in coal mines. A piece of land has already been secured by the British Home Office in the centre of the South Yorkshire coalfield where experiments along the lines mentioned are to be carried out. The idea has met with very general approval from mining men in Britain, and there can be little doubt that before long we shall have "permitted" safety lamps as well as "permitted" explosives in coal mines. In doing this the British authorities are only following in the steps of Continental Governments who long since adopted similar regulations. The circumstances surrounding the behaviour of safety lamps under varying conditions of pressure and amid certain explosive mixtures are more complex than might be thought at first, and definite data will be welcomed by all concerned, and particularly by the mine manager.

The Springhill Situation.

As forecasted in last fortnight's issue of the "Journal," the town of Springhill has been placed under the jurisdiction of a police commissioner, who arrived in the town with thirty picked constables on the 3rd of April. That it was high time the authorities took cognizance of the topsy-turvy condition of things in Springhill is evident from the fact that on the previous Saturday two of the town constables were arrested on a charge of interfering with the constables of the Cumberland Coal & Railway Company in the discharge of thoir duty, and were taken to jail. The appointment of a police commissioner is in some respects a strong measure, but it was necessary, and there should be no excuse for a state of affairs which allows men who are willing to work to be deterred from exercising their desire because of bodily fear and intimidation practised openly and in secret. Six strikers returned to work on the first day of April, making twelve during the same week. Most of these men were small property holders and types of the best class of miner in Springhill. There can be but little doubt that they, and many others, have been forced to remain out on strike because of the intimidation which has been allowed. That this is the case will speedily be shown when the new commissioner has taken charge.

In spite of the injunction against picketing made by the courts some time ago, this has been continued all along. A long list of defendants were arrested and tried for contempt of court. They were convicted, but an appeal was taken to the full bench in Halifax. The conviction has now been confirmed by the higher court, and an application to stay proceedings pending appeal to the Privy Council was refused. The defendants will therefore have to appear before the court for sentence.

A letter from the president and secretary of District 20 of the United Mine Workers of America has been sent to all the coal companies in Nova Scotia asking them to attend a joint meeting in Halifax on the 17th of April to draw up a wage schedule and agreement for the Province of Nova Scotia. This interesting communication, which is similar in contents to one sent out before the strike of 1909, concludes by stating that failure to attend the meeting will be taken as a refusal to consider a wage schedule and that the U.M.W.A. will take tho steps best calculated to achieve their object. When it is remembered that in Cape Breton the U.M.W.A. havo three unsuccessful strikes to their credit; that in Pictou County they have no following of any kind, and that in Cumberland County their influence is waning, it will be seen how farcical is the pose of this beaten and discredited organization as the representative of the miners of Nova Scotia. Some of the demands of the U.M.W.A. are understood to be the eight hours day, a minimum wage for labourers of $1.75 per day, and $2 per day for shift men.

The archaic platform of this organization is well set forth in a circular which has been widely distributed around the mining districts by the District Executive of the U.M.W.A. The opening paragraph of this leaflet postulates as follows:

"Hitherto the experience of the wage-earners of all countries and times, has been that every amalgamation of capital, every introduction of new machinery, has been made for the specific purpose of cheapening production by the elimination of numbers of wage-earners from the payrolls of their employers, and consequently resulting in an ever-increasing number of partially or wholly unemployed, and a gradual lowering of the

purchasing power of the earnings of those who do hold a job."

This is nothing more nor less than the ancient exploded doctrine which led to rick-burnings in our great-grandfathers' time, and is on a par with the remainder of the written and spoken eloquence of the organizers of the U.M.W.A. The miners of Cape Breton have had a hardly-earned lesson in the folly of listening to these strike-creators, and in the shameless self-aggrandizement and dishonest use of union funds practised by the leaders and organizers of the U.M.W.A. Many earnest and honest men who were beguiled into striking two years ago lost all they possessed, and suffered the degradation of license and idleness, and at the same time gradually opened their eyes to the fact that their so-called leaders were waxing fat and prosperous. It will be a long time before these men are again induced to strike for a shadowy grievance. The U.M.W.A. have shot their bolt in Nova Scotia, and missed the mark.

Dominion Coal Output.

The Coal Company's output for March was 323,869 tons, comparing with previous years as follows:

1908	346,529	1909	253,622
1910	243,747		

The individual collieries contributed as under:

No. 1	50,330	No. 9.....	31,607
No. 2	66,963	No. 10.....	14,706
No. 3	16,152	No. 12.....	21,574
No. 4	30,414	No. 14.....	8,432
No. 5	27,848	No. 15.....	1,834
No. 6	18,641	No. 16.....	754
No. 8	17,191	No.	323,869
No. 7	17,423		

This is a comparatively large output for March, particularly when it is considered that No. 6 and No. 3 mines were both idle for about a week to make extensive spring repairs. It will be noticed that the Lingan mines are steadily increasing in outputs, and that almost 33,000 tons of the total output comes from that district.

The prospects for open navigation during April are not of the best. The main body of Gulf ice has not as yet come down, and it looks as though navigation would be more interfered with by drift ice this spring than has been the case for several years past. Be that as it may, the April outputs will almost certainly be above the corresponding month of previous years, as the Coal Company has sufficient rail business to enable it to maintain shipments.

All indications are pointing towards a record year of coal shipments from Cape Breton. Both the Dominion Coal Company and the Nova Scotia Steel Company are anticipating larger outputs this summer than ever obtained previously, and these together with the unusually ample storage banks which have been accumulated during the winter, will, if no labour troubles arise, make the coming summer a very busy one in the coal business.

ONTARIO.

Cobalt.

Cobalt, April 8.—The Cobalt camp is still in the main tied up through the lack of customs power. This is the latest spring the North has known for some time, and not until the ice goes off the river will there be any relief. The trouble at the Cobalt Hydraulic plant at Ragged Chutes on the Montreal River commenced when the heads of the intake pipes blew out last fall, then followed low water and the consequent insufficient pressure to consumers in Cobalt. The Hydraulic now has storage dams on Temagami, and these will make the present condition of affairs impossible next year. At the present time the hydraulic pressure varies between 60 and 90 pounds, not sufficient to run the drills with any efficiency. Their customers who have large enough compressors, like the Coniagas and the Temiskaming, are using their own power entirely at the present time. Others, like the Nipissing and the La Rose, are supplementing what power they can get from the Hydraulic, with the power from their own compressors. But in this latter case operations have had to be restricted, and the output of the mine seriously curtailed. The operators worst hit by the lack of power are those who in view of the imminence of the customs power did not put any plant in at all. They have had to shut down entirely. The other customs plant serving the camp, the British Canadian, had an adequate service later than the Hydraulic, but the water has fallen so low now at their plant, at the Matabitchouan River, that there is absolutely no pressure at all. They neglected to make arrangements for the passage of logs over their storage dam, and the Government compelled them to open the dams and so let out the water. Next year there will be no trouble of this kind.

The ice is not likely to go off the rivers permanently until the end of this month, and until then the output from the camp as reflected in the shipments will be small.

The mines working in the immediate vicinity of Cobalt Lake have felt the effects of the failure of the air least. Proceeding from the Hudson Bay along the west ridge, the Coniagas, owing to the large compressor, was only affected for a few hours. Operations at the Buffalo have been so extended since the customs air was installed that the compressor is now insufficient and here mining has been curtailed to a considerable extent. The City of Cobalt has adequate power for its needs, and is now producing at a higher rate than at any previous period of its existence. The Townsite is also crippled to a considerable extent. On the other side of Cobalt Lake the La Rose with its subsidiary mines, the Lawson and the Princess, has felt the effect of the air trouble probably as much as any mine in camp. At the present time no development at either the Princess or the Lawson is possible, and the main La Rose has to furnish all the ore for dividend requirements. The Nipissing, with its half-dozen mines scattered over an area of two miles, has also found it impossible to carry on much development work. They, however, have such great ore reserves that it has only entailed the pulling down of stopes made some years ago. In the Kerr Lake area the Crown Reserve with its 22-drill compressor is also independent of the power companies. The Kerr Lake is considerably handicapped, however, and the Lawson and the Hargrave have had to shut down. In South Colemans the Beaver has only been able to run two drills. But this company is now installing the second half of its Rand compressor, so that in the future it will be quite independent of any air trouble. The Temiskaming has adequate power of its own. Owing to the air failure a number of promising prospects in this section of the camp, for instance the Ophir, the Lumsden, and the Fisher Eplett, have had to discontinue operations. Both companies have maintained the electric power for the mills, so that this very important department of the silver industry has not been in the least disturbed.

The production of the Coniagas for the months of February and March will make a record for this company. In the last two months in 1910 the Coniagas produced nearly 1,000,000 ounces. In the second and third months of this year this record will be considerably exceeded. For the past two years nearly all the ore from the Coniagas has come from development, now the ore previously put into sight is being taken down. The mill, the second largest in the camp, is treating on an average 75 tons a day, and making an excellent extraction.

From the Gowganda camp during the last ten days of March several shipments have been made. The Calcite Lake Mining Company, situated about seven miles from Gowganda, shipped between nine and ten tons. This is their first appearance on the list of producers. The Miller Lake O'Brien sent out about 20 tons of their high grade ore, while the Millerett despatched 22 tons. It is understood also that a few tons of ore went over the winter roads from the Hudson Bay claims, at Hangingstone Lake. All this ore came from below the 100-foot level. The Millerett would have made much larger consignments this

ar if they had not been more concerned with the building the mill than the mining of ore.

In the diabase section of the Millerett at Gowganda, excellent high grade ore has recently been struck at the 150-foot level. At the 70-foot level of this same shaft, the silver values in the smaltite vein were very low. The discovery that this vein in the diabase has become richer as it was sunk upon is considered a very important development in the camp.

The Beaver has now definitely joined the list of Cobalt dividend payers. There had been some debate as to whether the surplus on hand should be used in the erection of a concentrator or in the payment of a dividend. It was felt, however, that the erection of a mill was somewhat premature, and the mine is now gone on a 2½ per cent. basis.

Porcupine.

Excellent results have accrued from the development work on the 200-foot level of the Hollinger mine. The quartz vein here is, if anything, wider than that on the upper level, and the ore is now fully as rich. In all computations of ore in sight no estimate has been made of low grade ore in the mine, although it is known that the schist carries values. At least one parallel vein promises to add very considerably to the reserve. On the Vipond property, adjoining the Hollinger, there is now a drift of 150 feet at the 100-foot level, all in ore. The ore streak in the vein is about 3 feet wide, and the ore from this in the little Nissen mill is running about $40 to the ton. Outside this 3 feet there is a considerable amount of $10 to $1 ore. A cross-cut has been started to intersect the other parallel vein of the property. Operations on the Rea mine have added much in value to the Porcupine gold claims adjoining.

There has been a considerable influx of prospectors into what is known as the Keekeek country. Here something like 6000 acres have been staked under the Quebec laws. The pioneer in this district is Samuel LeRoy, with a good free gold find at Keekeek Lake. While the assays from the veins are not very high they are very consistent, and the veins are both larger and better defined than in Porcupine, or in any portion of the gold district so far prospected in Northern Ontario. Little work has been done so far on the claims. The field is easy of access in the summer time, and it is probable that the better terms the Quebec Government is offering prospectors will lead several thousand men who have been operating Ontario for the past two or three years to cross the provincial boundary.

ALBERTA.

Blairmore, Alta., April 4.—On March 31 the agreement between the miners in District 18 of the U.M.W.A. and the Western Coal Operators' Association expired by time limitation, and as the parties were unable to settle upon any basis for the signing of a new agreement nearly 6,000 miners ceased work on April 1. Sixteen mines with a daily output of 12,000 tons are closed by this action.

On March 2 the operators and district officials of the miners met in Calgary in joint conference for the purpose of negotiating the renewal of the agreement. On March 23 the operators presented the following resolution:

'That, whereas we have already spent upwards of a fortnight negotiating and have as yet arrived at no definite conclusions, and in view of the fact that the present agreements expire on the 31st of the present month;

'It is resolved that in order to prevent the possibility of a suspension of work on that date the following procedure shall govern each party to the negotiations which may take place between now and that date:

'1. That we proceed with the discussion of the agreement, and such clauses with any amendments or rates as we may agree upon to be embodied in and become part of the new agreement.

'2. Such clauses or rates as we may not be able to agree on to be set at one side and on the completion of our negotiations to be submitted to a Board of Arbitration for final adjustment.

''3. The finding of such Board of Arbitration to be binding and final and to be accepted by both parties.

''4. Said Board to be composed of two members appointed by the Western Coal Operators' Association, and two members to be appointed by District 18, U.M.W.A. and presided over by the Chief Justice of the Province of Alberta, or any justice of the Supreme Court of Alberta appointed by him.

''Meantime, should an award not be arrived at by the Board of Arbitration by the 31st inst., the miners will continue to work and the operators to operate their mines under the present agreements, and any award made shall apply as from April 1, 1911.

The miners did not agree to this, and then the operators presented the following offer for settlement:

''The general provisions of the Western Coal Operators Association agreement with the date of expiration fixed at March 31, 1913, and with the Discrimination Clause as at present and made a matter of record in the same way.

''An increase of 5.55 per cent. on all day wages of the Western Coal Operators' Association scale and on contract prices except on pillars and timbering.''

The next day, March 24, the miners submitted the following reply:

''In reply to the proposals of the operators we desire to say:

''1. We will sign no agreement that is conditional upon the relinquishing by ourselves of the closed shop as it exists at this time at the Crow's Nest Pass Company's mines, unless such a check-off clause as that presented by ourselves be made one of the terms of the agreement.

''2. That we will not agree to the general application of such a discrimination as now applies to part of our membership.

''3. That the advance offered is not general and only applies to part of the employees.

''4. That the advance quoted is not sufficient to bring men employed on the day wage scale up to the rates paid in adjoining districts.

''5. That no provision is made for the eliminating of inequalities at the mines already specified.

''6. That no provision is made for the fixing of contract rates on mines where no contract rates exist, prior to the signing of the agreement.

''7. We desire to state that our proposition is definitely as stated in our first proposals with the following modification in Clause 4 to be changed: 'An advance of 12½ per cent. on the present day wage scale, after existing inequalities in the district are adjusted.' Clause 7 to be changed. The date of expiration of the agreement to be March 31, 1913.' ''

As this was not satisfactory to the operators, the miners then moved to adjourn sine die, and up to the present no efforts have been made looking to a renewal of negotiations.

BRITISH COLUMBIA.

The construction of railways now in progress in districts of the Province in which economic minerals are known to occur gives promise of facilitating the further development of the large mineral resources of British Columbia. The extension by the Great Northern Railway Company of what is known locally as the V. V. & E. line from Keremeos, through Hedley, and thence to Princeton, is resulting in the opening of several coal mines near or beyond Princeton, notably those of the Princeton Coal & Land Company, which last year commenced production on a commercial scale, with an output of nearly 12,000 short tons of coal; and of the Columbia Coal & Coke Company, which is developing a valuable coal property situated between Granite Creek and Tulameen (Otter Flat). The Princeton Collieries, Osoyoos Coal Company, and two or three others have also been encouraged by the construction of this railway to proceed with prospecting work and development of their respective properties. A cement manufacturing enterprise has been started in this district, while the opening of a number of copper claims is also looked forward to.

In Nicola district, the construction of the Kettle Valley Railway is in progress; this is intended to connect this district, in which are productive coal mines, with the Boundary district, regarded as sure to prove a profitable market for coal and coke from Nicola collieries. There is expectation, too, that copper mines will be opened in parts of the country this railway will traverse. Toward the eastern end of the Kettle Valley Railway there is the West Fork of Kettle River district, in which, as well as in the Nicola country, much prospecting has disclosed the occurrence of metal-bearing ores, though the West Fork claims that have as yet had most attention contain value in gold or silver rather than copper.

In East Kootenay, the construction of what has heretofore been known as the Kootenay Central Railway, southwards from the Canadian Pacific transcontinental at Golden, B.C., up Columbia River to the lakes at its source and thence down the valley of Kootenay River to a junction with the same company's Crow's Nest railway, is being proceeded with. Work on the most southerly section of this line has been in progress for some time; recently a contract was let for about 40 miles of the northern end, work on which in past years consisted of grading about 10 miles south out from Golden. In Windermere mining division, approximately half way between Golden and the Crow's Nest line, there are a number of mining properties, chiefly silver and lead, several of which were worked years ago, and from which ore was shipped but at too high cost to admit of production being continued under such unfavourable conditions. Here, too, the provision of railway transportation, though intended primarily for the development of an agricultural industry in a comparatively large area of fertile country, will serve to promote the utilization of mineral resources believed to be extensive and capable of being worked to advantage.

It is yet early to estimate the effect on mining the construction of the Canadian Northern Pacific Railway, from Alberta through the Yellowhead Pass and thence down the North Thompson River to Kamloops, on its coastwards route, will have, but at least two beneficial results to this industry are expected, namely, the making more accessible the mica claims in the country about Tete Jaune Cache, and giving transportation to the North Thompson district, in which coal is stated to occur. As the country between Kamloops and the Coast has long had the benefit of the C.P.R. passing through it, no particular additional advantage is likely to accrue to the mining interests by the construction of a second railway.

On Vancouver Island, both the C.P.R. and Canadian Northern Pacific Companies are busily engaged in railway building. The work of the former is well advanced; that of the latter has lately been commenced. In both cases, country in which mineral occurs will be opened to prospectors to an extent that will encourage much more exploration work being done than in the past. Much of the country is mountainous and heavily forested, but this notwithstanding, prospecting will be rendered less difficult and costly after construction of the new railways, and the eventual opening of valuable deposits of mineral may be expected. Fortunately, the more important of the known coal fields of the Island are within easy reach of tidewater, so that with only the construction of short lines necessary, they have already been provided with transportation from the mines to shipping ports. It is in connection with the discovery and development of metalliferous minerals more particularly that the mining industry of the Island is likely to be benefitted.

The great extent of country in northern Cariboo, Omineca, and Skeena mining divisions that will be opened for mining development by the construction of the Grand Trunk Pacific Railway, now well on towards completion, contains immense and varied mineral resources from which in the course of a few years there will probably be a considerable addition to the value of the annual mineral production of the province. Placer gold, lode metals, and coal, are all to be found in that central part of British Columbia, and the provision of transportation facilities will doubtless be followed by much mining on commercial basis.

In smaller measure, the McKenzie & Mann Railway fro Stewart, at the head of Portland Canal, inland, will assist the development of mining further northwards. A beginni has been made by giving the mining properties near Stewa railway connection with the sea, and if the suggested extensi of the line into the Nass River country, and thence eastwar to the Peace River district be carried out, another large ar of practically virgin territory will be opened to prospecto and miners, with reasonable ground for expectation of su stantial results in the direction of mineral production.

There are other railway construction projects that, if und taken, may be expected to add to the volume and value of t mineral production of British Columbia (among them one th has been commenced and intended to connect the Lillooet d trict with Howe Sound, thereby opening another mining d trict.) Those mentioned above will, however, of themselv be sufficient to indicate that considerable expansion may looked for in connection with mining in British Columbia, well as with its other large and valuable natural resources.

Ore Production to March 31.

In a general way, the ore production of the Kootenay a Boundary districts is shown by the figures that follow. these notes are being written before the returns for the l week of the quarter have been received, the figures are exact, but, though approximate, exhibit fairly closely the qu tities of ore produced in the several parts mentioned.

As the Boundary district is, in regard to ore tonnage, far the most productive in the province, its proportion of whole having of late years been nearly three-quarters, it ne sarily is a long way in the lead for the short period under view. Roughly, the output for the three expired months of year has been 450,000 tons of ore, of which quantity the Gr by Company's mines have produced 293,000 tons, those of British Columbia Copper Company 127,000 tons, and of Consolidated Mining & Smelting Company 30,000 tons. Sev small shipments were made by other mines, but in compari with the foregoing they are unimportant. The Granby C pany's production has been all from its group of big mi at Phoenix; the British Columbia Copper Company mined at 82,000 tons at its Mother Lode mine, 9,000 tons came from Wellington camp property, and 36,000 tons from the Rawl mine of the Dominion Copper Company's group, now contro by the B. C. Copper Company. The quantity from the Denoro mine was small, while that from the Napoleon is taken into account, this mine being situated in the adjoi State of Washington. The Consolidated Mining & Smel Company sent to its smeltery at Trail about 27,000 tons f its Snowshoe mine, 2,400 tons from the Phoenix Amalgam group, and 700 tons from the No. 7 mine. The Phoenix A gamated had not previously shipped ore; the group is situ immediately south of the southern claims of the Granby C pany's group. Late in March the Fife mine, in the extr eastern part of Grand Forks mining division, made its shipment in bulk, of copper gold ore, but it was only a s beginning.

Rossland mines made a total production of approxima 58,000 tons during the quarter. Of this quantity, 44,000 of gold-copper ore was from the Consolidated Company's tre Star group, about 10,200 tons from the Le Roi No. 2 cluding 3,600 tons of second class ore concentrated at the mi and 3,600 from the Le Roi. From four or five small mines t was a total of about 220 tons, of which quantity 174 tons from the Nickle Plate mine now worked in a small way leasers, but years ago one of the important mines of Ross camp. The expected production from two or three silver properties in this camp has not yet been realized, excep very small measure.

East Kootenay mines have a total shipped of between 10,000 and 11,000 tons sent to the smeltery, and perhaps a rather larger quantity concentrated at the St. Eugene mill. The former total includes 1,600 tons of silver-lead concentrate from the mine. The quantity appearing in provincial newspapers as having been milled at the St. Eugene is far in excess of that actually put through the concentrator. The output of the Sullivan mine, which together with the St. Eugene is operated by the Consolidated Company, was about 9,000 tons. The Society Girl sent between 200 and 300 tons to Trail before the melting snow made the waggon road too soft for hauling ore to the railway. This mine commenced shipping on a small scale late last year; some years ago ore was taken from its surface workings, but recent production has been from underground.

The tonnage for Nelson mining division includes so much ore treated at local stamp mills that figures published are not reliable as a rule. The actual quantity shipped to the smeltery, including concentrates from the stamp mills, was between 3,700 and 4,000 tons. Mines near Nelson city contributed more than 400 tons, those at Ymir (chiefly from the Yanke Girl group), 1,300 tons, the Emerald at Salmo about 900 tons of lead ore, Erie mines, 200 to 300 tons (figures not available), and Sheep Creek 850 to 900 tons. The last-mentioned in no way represents the quantity of ore milled at the Queen and Nugget stamp mills; only the product sent to the smeltery from the several shipping mines of the camp.

Ainsworth and Slocan together have a total of nearly 4,500 tons, which does not at all fairly represent the producing capabilities of these districts, for there were no concentrating mills at work, consequently the figures show only the first-class ore shipped. Several small mines in Ainsworth camp made a combined output of nearly 200 tons. Slocan mines inland from the lake sent out 1,700 tons, chiefly from the Rambler-Cariboo and Richmond-Eureka properties. Slocan Lake mines shipped 700 tons, mostly from the Standard, with about 180 tons from Slocan City division. The Lardeau district shipped 190 tons in all.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax, March 31st.—With the election of officers the 19th annual meeting of the Mining Society of Nova Scotia was brought to a close yesterday afternoon. The new president is G. J. Partington, who is identified with the gold mining industry.

At the morning session Professor E. A. Holbrook read a paper on "Modern Gold Mining Practice and its Application in Nova Scotia." Another paper was read by W. F. Jennison, whose subject was "Gypsum." This is the first paper relating to gypsum read before the Mining Society.

The only other paper read was one on "Coal Mining," by M. Dowling, of the Dominion Geological Survey.

During the afternoon a number of interesting papers were read. Dr. Ora W. Knight spoke on research work on certain Nova Scotia gold mines. C. J. McKenzie told how to handle the coal dust problem. W. H. Prest read a paper on "Prospecting in Nova Scotia," and John Preston described a "Light Weight Motor Driven Reciprocating Pump."

The officers elected were:

President, G. J. Partington.

First Vice-President—Prof. Sexton.

Second Vice-President—Thos. Cantley.

Council—C. E. Starr, Hiram Donkin, R. H. Brown, H. E. Cl, A. L. McCallum, A. A. Hayward, Hon. R. Drummond, G. W. Stuart, John Johnston.

Halifax, April 4—Major Thompson, Provincial Police Commissioner, left yesterday for Springhill, with his force of 33 Provincial police. The Commissioner and his men will replace the R. C. R. detachment, which will return the first of this week. They will be housed in "barracks" and will do, in the capacity of civil police, what the military force has been doing for the past year. The party left on the C.P.R. express.

Springhill Mines, April 2.—It now looks as if the strike in Springhill was drawing to a close. Five of the leading miners returned work yesterday. Thomas Piggott and Duncan Blue were among the number. These men have been for many years residents of Springhill and have always stood with their fellow workmen. It is stated that a large number of others have applied for work, and have accepted the terms of the company.

During the coming week a big break in the ranks of the strikers is predicted. The town was exceptionally quiet on Saturday, there was no picketing nor any disturbance of any kind. The officials of the company are confident that the beginning of the end is rapidly approaching.

As a result of the judgment of the Full Bench of the Supreme Court on Saturday, the Springhill miners who were found guilty of violating an injunction against picketing, will now have to come before the court for sentence. Seven or eight men are involved.

The case was that of the Cumberland Coal & Railway Company vs. McDougall, an appeal from the decision of one of the judges. The court dismissed the appeal with costs.

W. B. A. Ritchie moved for an order not to enforce the judgment pending an appeal to the Privy Council. The motion was refused.

New Glasgow, April 4—New record outputs in nearly every department were made by the Nova Scotia Steel & Coal Company for the first quarter of 1911.

At all the Scotia plants the outputs since the New Year have been excellent, and increases of from 20 to 40 per cent. over the production for the same period of 1910 have been shown, due to the extensive improvements recently installed.

The most marked increases have been made at New Glasgow. The Cogging mill rolled 19,540 tons of billets during this period, an increase of 25 per cent., while the finishing mills produced 15,232 tons of bars and plates, nearly four thousand tons more than in the corresponding quarter of 1910, while the production of pig iron was 20,546 tons, six thousand tons better than last year.

A number of new records were made during March. The Cogging mills which made a record of 6,600 tons in February, exceeded this by six hundred tons, while the finishing mills, which in February established a record of 5,000 tons, exceeded this by 500 tons. Further improvements are now in progress at the various plants which should increase the outputs even more proportionately, and if the present record is maintained the outputs for 1911 will far exceed the records made in 1910.

ONTARIO.

Cobalt—The Beaver mine is now a dividend-payer. The first dividend of 2½ per cent. is payable May 15.

Copper Cliff.—Captain John Lawson has quite recovered from his illness and is back at his post of duty with the Canadian Copper Company.

BRITISH COLUMBIA.

Trail.—At the Trail smelter during March, 6,000 tons o lead ore were smelted, yielding 1,500 tons of lead. For th Kootenay district bounty will be paid upon 17,000 tons for th fiscal year ending March 31st.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending March 25, and those from Jan. 1, 1911, to date:

	Mar. 25. Ore in lbs.	Since Jan.1. Ore in lbs.
Beaver	43,730	595,243
Buffalo	129,170	623,670
City of Cobalt	44,000	296,280
Coniagas	120,910	1,055,090
Crown Reserve	40,060	548,730
Hudson Bay	63,600	185,950
La Rose	59,780	1,165,500
Kerr Lake	120,106	841,698
McKinley-Darragh-Savage	100,110	1,420,150
Nipissing	132,720	1,738,960

The shipments for the week were 863,186 pounds, or 431 tons.

Following are the shipments from the Cobalt camp for the week ending Mar. 31, and those from Jan. 1, 1911, to date:

	Mar. 31. Ore in lbs.	Since Jan.1. Ore in lbs.
Barber	.....	6,000
Beaver	.....	595,243
Buffalo	61,190	684,860
Chambers-Ferland	64,000	320,900
City of Cobalt	.....	296,280
Cobalt Lake	58,900	1,205,800
Cobalt Townsite	.....	289,740
Coniagas	111,300	1,166,390
Crown Reserve	.....	548,730
Hargraves	.....	41,100
Hudson Bay	.....	185,950
La Rose	.....	1,165,500
Kerr Lake	.....	841,698
King Edward	.....	40,000
McKinley-Darragh-Savage	.....	1,420,150
Millerett	44,000	44,000
Nipissing	81,800	1,820,760
O'Brien	64,120	335,440
Peterson Lake (Little Nip.)	.....	58,430
Right-of-Way	.....	318,260
Silver Cliff	.....	98,180
Standard Cobalt	.....	44,813
Temiskaming	140,193	503,612
Trethewey	45,500	275,200
Wettlaufer	.....	60,022

The shipments for the week were 671,003 pounds, or 335 to

The shipments from Jan. 1 to March 31, were 12,469,0 pounds, or 6,234 tons.

BRITISH COLUMBIA ORE SHIPMENTS.

The following are the returns of the ore production a movement for the past week, ended March 25, and for t year to date:

BOUNDARY SHIPMENTS.

Granby	27,817	265,(
Mother Lode	7,056	74,(
Snowshoe	2,424	24,(
Rawhide	1,443	34,(
Jack Pot	805	7,(
Number Seven	27	(
Phoenix Amalgamated	102	2,(
Fife	32	
Other mines	.....	
Total	39,706	410,

ROSSLAND SHIPMENTS.

Centre Star	3,346	40,
Le Roi No. 2	726	5,
Le Roi No. 2, milled	300	3,

Prompt and Satisfactory Returns

The North American Life is continually receiving from policyholders unsolicited letters like the following, expressive of their appreciation of the treatment accorded them and results attained:

The holder of Policy No 8192 wrote:—
"I appreciate the promptness with which you have remitted the amount due me. I may say that I have nothing but praise for your company for the very satisfactory way in which I have always been treated. Our business relations have been very pleasant and I wish the North American Life the future success it so well merits."

The holder of Policy No. 9205 said:—
"I cannot close matters with the company without expressing my great appreciation of its methods and the very fine manner in which I have been treated by its representatives. In the 20 years of dealing I can recall no single instance in which I have received anything but courtesy and business promptness. I hope to renew relations with the North American soon in respect to my children's insurance."

The Financial Position of the Company is Unexcelled.

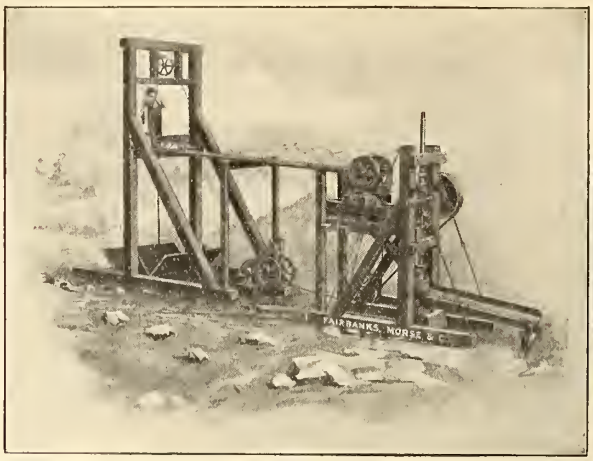
Prospector's Outfit

Fitted with NISSEN STAMP MILL



Nissen Mortar

A Boon to Prospectors

A simple, compact outfit, sturdy in construction and which is easily taken apart for transportation purposes. One man and a supply of gasoline is all that is necessary to operate the outfit.

It is fitted with a Fairbanks-Morse Gasoline Engine, which cannot be equalled for reliable continuous service. The stamp mill is a modern Nissen Stamp—the mill with largest capacity and smallest consumption of Power. Our Bulletin will tell you all about it. Send for it to-day.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Address P.O. Box 331
Toronto, Canada.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definately the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.

NEW BRUNSWICK and NOVA SCOTIA

1107. Joint Report on the Bituminous or Oil Shales of New Brunswick and Nova Scotia. Also on the Oil Shale Industry of Scotian Part I, Economics, Part II, Geology by R. W. Ells.

QUEBEC

1077. Memoir No. 7, Geology of St. Bruno Mountain, Quebec, with maps, by J. A. Dresser.

ONTARIO

1059. A Geological Reconnaissance of the region traversed by the National Transcontinental railway between Lake Nipigon and Clay Lake, Ontario. Accompanied by two maps covering the region, by W. H. Collins.

1082. Memoir No. 6. Geology of the Haliburton and Bancroft Areas, Ontario, by Frank D. Adams and Alfred E. Barlow.

1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.

NORTH WEST PROVINCES

1035. Coal Fields of Manitoba, Saskatchewan, Alberta and Eastern British Columbia accompanied by a map, by D. B. Dowling.

1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1093. Memoir No. 2. Geology and Ore Deposits of Hedley Mining District with maps, by Charles Camsell.

1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1101. Memoir No. 5. Lewes and Nordenskiold Rivers Coal District, Yukon Territory, by D. D. Cairnes.

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.

1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1902, by A. W. G. Wilson.

MAPS RECENTLY ISSUED:

CANADA

1104. Map 11A. Braeburn-Kynocks Coal Area, Yukon Territory. Scale 2 miles to 1 inch.

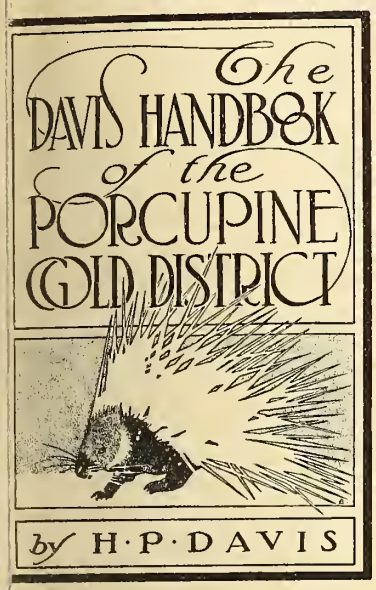
NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 1 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

IN PREPARATION

THE DAVIS HANDBOOK



OF THE Porcupine Gold District

THIS BOOK WILL INCLUDE:

A.—An accurate and up-to-date map of the Porcupine Gold District.

B.—A brief review of the discovery and development of the Northern Ontario mining districts, including an analysis of the production and dividends of the Cobalt camp to December 31, 1910.

C.—A historical sketch of the discovery and early development of the Porcupine Gold Fields.

D.—An outline of the geology of the Porcupine area.

E.—A description of the important properties so far developed.

F.—A directory of the incorporated companies, giving the date and place of corporation, the head office, transfer office, capital authorized and issued, officers and directors, the location and area of the property, equipment, development, etc.

This book will be illustrated with many photographs and drawings, and will be printed on high grade paper with heavy paper or cloth covers. The first edition will consist of 5,000 copies.

Companies and syndicates operating in the Porcupine Gold District are requested to send full information to the publisher. Blank forms will be furnished on application.

Orders sent to H. P. DAVIS, 25 Broad Street, New York, will be filed and notifications will be sent when book is ready for distribution.

Price, Paper Cover, $1.00, Including Map. Price, Cloth Cover, $1.50, Including Map

CLYDE PATENT WIRE ROPE WORKS

Rutherglen, Glasgow, Scotland

WIRE ROPES

For Winding and Haulage in Collieries and Mines, Aerial Ropeways, Transmission of Power, Suspension Bridges, etc. SPECIALLY FLEXIBLE ROPES for Hoists, Winches, Loading and Discharging Cranes, Shipping Purposes, Towing, Alligator and Dredger Ropes, etc. SPECIAL ROPE FOR LOGGING.

Our Ropes are made from wire drawn for our exclusive use, and are at work all over Canada. Messrs. Nova Scotia Steel & Coal Co., Ltd., who use them largely, write that one of our haulage ropes at their Wabana Mine has been in use for **5 years**, drawing over 1,750,000 tons and still in good condition. From the Atlantic to the Pacific they are well known and our agents will be only too pleased to give all information to enquirers. They may be had from the following, viz:

Nova Scotia: Wm. Stairs, Son & Morrow, Limited. New Brunswick: W. H. Thorne & Co., Limited.
Montreal and Toronto: Drummond, McCall & Co. Vancouver, B.C.: John Burns. Winnipeg: David Philip, Portage Ave.

HIGHEST Quality. MODERATE Price. Prompt Delivery. SATISFACTION in use.

Cables: "Ropery, Rutherglen." Codes: A. B. C. (4th and 5th Editions), A.I., Liebers and Private

MINING AND SCIENTIFIC PRESS

Established 1860 Published weekly

Controlled by A. Rickard H. Foster Bain, Editor Thomas T. Read, Associate Editor

In every issue valuable articles are published on mining, metallurgy, and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor Published monthly at London, England

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

COMBINATION RATE: To new subscribers to both papers in Combination yearly rate

Canada U. S. and Mexico,	$6.00
United Kingdom	7.00
Other countries in Postal Union	8.00

Address either office:—
MINING AND SCIENTIFIC PRESS, 667 Howard St., San Francisco
THE MINING MAGAZINE, 819, Salisbury House, London, E. C.

Hotel Shuniah

PORCUPINE

THE only High-class Hotel in the Gold Fields, and being enlarged to accommodate the numerous patrons now coming in. The "Shuniah" will then be in a position to give first-class modern service.

An Enquiry Bureau in connection with the Hotel has been opened, and also a competent Stenographer engaged for the benefit of our many Guests and Visitors.

School of Mining

A COLLEGE OF APPLIED SCIENCE

AFFILIATED TO QUEEN'S UNIVERSITY

KINGSTON - ONTARIO

1. Four Years' Course for a Degree (B.Sc.)
2. Three Years' Course for a Diploma in
   - (a) Mining Engineering.
   - (b) Chemistry and Mineralogy.
   - (c) Mineralogy and Geology.
   - (d) Chemical Engineering.
   - (e) Civil Engineering.
   - (f) Mechanical Engineering.
   - (g) Electrical Engineering.
   - (h) Sanitary Engineering.
   - (i) Power Development.

For Calendar of the School and further information apply to The Secretary, School of Mining, Kingston, ∴ ∴ ∴ Ontario

Michigan College of Mines

F. W. McNair, President

Located in the Lake Superior district. Mines and mills accessible for College work. For Year Book and Record of Graduates apply to President or Secretary.

FACULTY OF APPLIED SCIENCE AND ENGINEERING

Courses in

1. Civil Engineering.
2. Mining Engineering.
3. Mechanical Engineering.
4. Architecture.
5. Analytical and Applied Chemistry
6. Chemical Engineering.
7. Electrical Engineering.

For Calendar and other information apply to the Secretary

A. T. LAING.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unsurveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minimum being 40 acres in unsurveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries
Quebec.

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTI

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native orm; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Sil; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Miner; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. It **does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appear ance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines

Nobel Monobel, Saxonite and Carbonite.

THE CORE TELLS

The accompanying photograph shows four sections of a diamond drill core recently secured in drilling for limestone near Auburn, California, by the Mountain Quarries Co. The average length of the cores is nine feet four inches, and their diameter, $\frac{15}{16}$ of an inch. They were removed with a Sullivan "Class H" Diamond Drill, using a ten foot core barrel. The cores, it will be noted, form a perfect record of the rock formation from which they were cut.—"MINE & QUARRY."

THE Core tells where your ore or coal is, what it is worth and how best to reach it. It tells these things with a accuracy that cannot be doubted, and more quickly an cheaply than you can obtain this knowledge in any other way

Amatite ROOFING

"NEEDS NO PAINTING."

AMATITE means more to the man who needs a roofing than just merely something to put on the top of a building.

It means a thoroughly satisfactory and reliable roof covering, without future *expense for painting* — because the *real mineral surface* makes painting unnecessary.

Frequently the cost of painting a roofing amounts to almost enough to buy a new Amatite Roof.

Amatite can be laid right over shingles, tin or other ready roofings. The directions hold good for laying Amatite anywhere and over anything, and are as simple as A B C.

For further information, booklet, samples, etc., address nearest office.

Everjet Elastic Paint

A very tough, durable paint at a low price. One color only—lustrous black. Use it for machinery, heating apparatus, smokestacks, roofs, fences, water tanks, etc.

Creonoid Lice Destroyer and Cow Spray

Cows give more milk if sprayed with Creonoid to keep away the flies which make them restless. The poultry output will be increased if the hen house is made obnoxious to insect pests by disinfection with Creonoid.

RAND "B.C. 11"

HAMMER DRILLS

The Telescope Feed Hammer Drill is rapidly displacing the heavier types of piston drills for stopping and drilling all "up" holes. purely on the strength of their lighter weight simple and easy operation; saving in air consumption; saving of time in changing steels, changing positions and starting new holes; reducing labor costs and their adaptability to places difficult of access. If you have not seen the New "B.C. 11" or Butterfly type of drill you should write for our descriptive pamphlet at once.

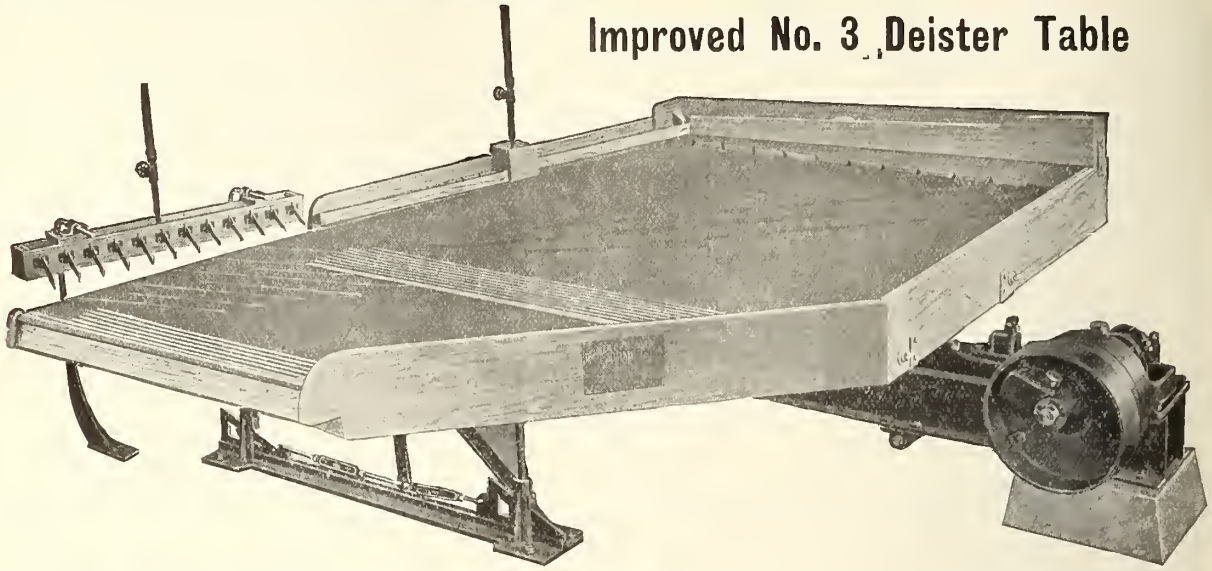
Improved No. 3 Deister Table



THE vanner has been a most efficient type of concentrating device for a decade. Competitive tests in such well known mills as **Goldfield Cons. Mines Co., Goldfield, Nevada; Miami Copper Co., Miami, Arizona; Stratton's Independence, Ltd., Victor, Colorada; Old Dominion Copper Co. Globe, Arizona** and **Detroit Copper Co., Morenci, Arizona,** have proven the Improved No. 3 Deister Table superior in efficiency on feeds of 80 mesh and finer. A pleased customer remarks: "Your No. 3 Table does as good work for us as vanners at a tithe of the cost for repairs."

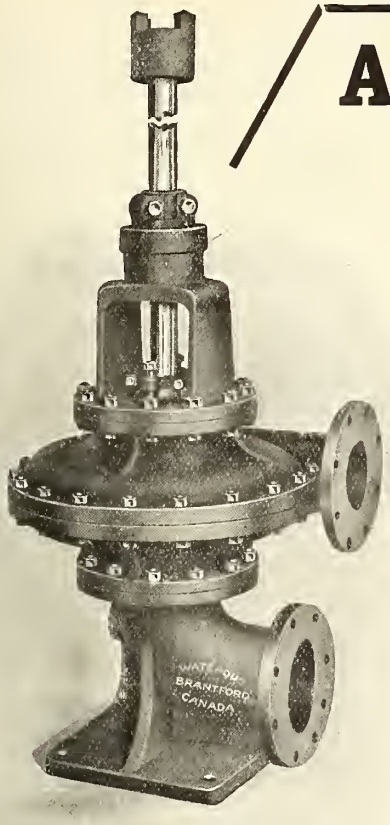
KINGSTON, ONT.



A Waterous Pump for Mine Work

It is simple in construction. It is built of few parts, there are no valves to get out of order, no restricted water-passages to clog up ; there is not a complicated piece in its whole make-up.

It is built strongly throughout. Wherever wear is likely to occur the casting is re-inforced and strengthened to resist it. The materials used are selected, and the careful way parts are put together prevents wear and consequent slackness.

It is easy to operate. It can be left in care of an unskilled laborer without danger. All that is necessary is to start it running and to shut it off when the whistle blows. Overhauling and cleaning are made simple by the split-base and split packing gland—special features of this pump.

It is compact and comparativety light. It can be quickly and easily moved from place to place and will work well in any position.

The pumps are built in Horizontal and Vertical types. In sizes up to 14in. discharge opening. Are adapted for Belt, Engine or Motor Drive.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

BEHREND DRY CONCENTRATOR

DRY and WET CONCENTRATION

NOTE:—OUR *NEW* TESTING PLANT is capable of treating 10 tons of ore per day, and is equipped to test any kind of ore, having all necessary appliances, such as Driers, Crushers, Rolls, Sizing Screens, DRY CONCENTRATORS, FLOTATION CONCENTRATORS, and WET MULTIPLE CONCENTRATORS. ALSO a MODERN LABORATORY and MECHANICAL DEPARTMENT with competent staff under the supervision of an expert engineer and analyst.

Send us small sample of ore for our preliminary report.

CANADA'S ASBESTOS INDUSTRY.

There has just been issued by the Mines Branch of the Department of Mines, Ottawa, a 300-page illustrated monograph on the asbestos industry. This is a second and much more complete edition of a former volume issued in 1905. Mr. Fritz Cirkel is the author of both.

Under title, "Chrysotile-Asbestos—Its Occurrence, Exploitation, Milling, and Uses," Mr. Cirkel has endeavoured to review the whole Canadian industry in all its economic aspects, and to touch upon the production of the mineral in other countries.

In the first two chapters the reader is told of the general historical, physical, and geological facts relating to the Canadian mineral. The third chapter discusses the quarrying of asbestos. Here we note with approval the substitution of the word "quarrying," in place of "mining." Only one MINE of asbestos is worked. That is the well-known Bell mine at Thetford. All other workings are quarries. Mr. Cirkel predicts the continued use of both quarrying and mining, and expresses the belief that only the richer properties will employ mining methods. He asserts further, that mining will be conducted on approved rich ground. The chapter presents an interesting resume of general ore winning practice.

A very useful synopsis of milling practice is contained in the fourth chapter. Probably some of the illustrations could have been omitted with advantage. However, there is much important information given. The costs of construction, labour, and operation are set forth. Particularly noticeable is the marked diversity in the flow sheets of various mills. Standardization has not yet been nearly attained.

A conspectus of mining, milling, and marketing costs follows. Certain advantageous features of the Quebec asbestos regions are touched upon. The remarkable fact that there is no working quarry situated farther than 1½ miles from the railway line, is mentioned. As to the future of the industry, Mr. Cirkel believes that, although geographically the field is strictly limited, yet there are such enormous indicated reserves that there is little need of worrying. He quotes one instance to which we must take exception. In one Black Lake quarry, he asserts, there are 44,377,500 tons of asbestos rock in sight. Deducting 50 per cent. from this as waste rock, we have roughly 22,000,000 tons of mill rock left, or a supply sufficient to keep a plant of 4,000 tons daily capacity running for

more than twenty years. The exception that we would take to this statement relates rather to the form than to the matter. That there may be 44,000,000 tons of asbestos rock indicated between several present workings we do not doubt. But that this ore is literally, in an engineering sense, in sight cannot be the case. It is, of course, quite justifiable for men who know the region to spend money upon the assumption that large intervening blocks of ore are homogeneous to the depth attained by the present workings. In fact, the probability of this being the case may be higher than in many instances where metalliferous veins are blocked out on three, or even four, sides. But it is quite incorrect to term such assumed reserves "ore in sight." This is, after all, a matter of terminology. It is, nevertheless, highly important to avoid even the suspicion of exaggeration.

A comprehensive descriptive directory of mines and prospects occupies the next forty pages. Then come chapters on foreign asbestos and commercial uses, and an appendix by Mr. Frederic Bacon on the testing of heat-insulating materials.

* * * * *

We have sketched very meagrely the ground covered in this monograph. The book includes facts and data not otherwise obtainable. It is comprehensive and complete. The author has gone to no small pains to walk circumspectly. He has had an especially complex subject to attack. We believe that he has done his work creditably. The new monograph is a distinct improvement upon the first edition. More careful editing would have been well. But, all in all, the publication is to be warmly commended.

A MIDWINTER JAUNT.

Several weeks ago there appeared an item in the newspapers announcing that Mr. R. J. Flaherty had returned from Hudson Bay, and that he had brought with him the diaries, field-notes, etc., etc., lost during the previous summer by Prof. C. K. Leith. No further mention of the matter has been made.

As Mr. Flaherty's journey was remarkable in many respects, we shall present here a few details. A more complete description will appear later. Even the bare outline, however, is most interesting.

Mr. Flaherty, who is a very young man indeed, left Cochrane, a station on the Temiscaming and Northern Ontario Railway, on August 28, 1910, with one white companion. Moose Factory was reached by the Mattagami route on September 5. Here a boat was engaged and on September 7th Mr. Flaherty landed on Charlton Island. Not until the 25th, however, did he succeed in making arrangements to sail to Fort George. Eight days of sailing brought him there.

Further progress was now impossible. A long wa was necessary until travelling by dog-team becam practicable. Finally, on December 16th, Mr. Flahert set out for Cape Jones with no white companion. A Cape Jones he engaged two Esquimaux and a tea of nine dogs. Despite bad ice conditions, he mad Great Whale, the most northerly Company post o the east coast of Hudson Bay, on Christmas night. Tw days were spent here in arranging with the half-bree in charge for another relay of Esquimaux and dog On New Years Day, Little Whale, an abandoned pos was sighted. It had taken five days to travel 70 mile On January 4th Nastapoka Sound was reached.

After making a seven days' examination of certa of the Nastapoka Islands, Mr. Flaherty started on h return journey. While travelling with an Esquimau family, a short stop was made at Little Cape Jone In the igloo of an Esquimau entitled Husky Bill, label much more pronounceable than the gentleman native patronymic, Mr. Flaherty was astonish to see a very modern cross-section book. H curiosity was aroused. Upon inquiry he found o that the book belonged to Dr. C. K. Leith. Furthe he discovered that Dr. Leith's dunnage bag had be picked up on the shore by Husky Bill's son, near Litt Cape Jones, after being exposed to the weather f some months. He found the notes, etc., in perfe condition. The contents comprised diaries, geologic notes and sketches, six fifty-dollar drafts, and $53 cash. The Esquimaux gave up the bag witho demur.

Mr. Flaherty now proceeded south; getting to Fo George on January 23rd. Since leaving that post had covered about 600 miles under desperately adver conditions. The actual time occupied was five weel which period included all stops and delays.

The return route to Moose Factory was made mu longer than necessary as the Esquimaux refused travel directly to Moose on account of the deep sno So it was possible only to strike out for Rupert House. An Indian dog-team was engaged here. Lea ing Moose Factory on March 2nd, Mr. Flaherty a rived at Cochrane on March 14th. Thus between I cember 16th, 1910, and March 14th, 1911, he had co ered 900 miles on ice and 200 miles on land.

The recovery of Dr. Leith's manuscripts and no books is an incident that reads like highly colour fiction. No doubt that distinguished geologist h given up all hope of seeing his precious bag aga Incidentally, the story affords a pleasant illustrati of the honesty of the unsophisticated Esquimau Apart, however, from this accidental piece of luck, M Flaherty's performance as a sub-Arctic traveller is u usually noteworthy.

Leading authorities, especially on the other side the Atlantic, predict continued low prices for copp

E RESIGNATION OF DR. R. W. RAYMOND.

personality stands out more prominently in all merican mining world than that of Dr. Rossiter aymond. For forty arduous years he has been tstanding figure in the affairs of the American ute of Mining Engineers. After filling the offices ce-president and president during several suce years, Dr. Raymond was elected secretary in His annual re-election has been taken as a matcourse.

secretary of one of the most important technical ations in the world, Dr. Raymond has perd his duties without fear or favour. In his ity as editor of the transactions, he has been the g spirit in collecting and preparing for publia vast bulk of professional literature. All the lical excursions of the Institute have been sucl largely because of the zeal, courage, and ine of Dr. Raymond.

announcement that Dr. Raymond has resigned sition will be read with sincerest regret by his rous Canadian friends. However, it is distinctly ling to learn that Dr. Joseph Struthers is to be ccessor. Dr. Struthers has long occupied the on of assistant-secretary. He is fitted in every t to carry on the work of the Institute.

hing could be more fitting than that the Can- Mining Institute should seek the opportunity of g in any steps that may be taken to honour the ng secretary.

"VALUES."

irrepressible contemporary, The Mining Magais at it again. In the current issue of that inble periodical is a strong editorial objection to n uses of the word "values" in mining engineers' s. Academically, The Mining Magazine is right. ically, it is partly right and partly wrong. And, dly, this kind of thing may be defined as "placritating emphasis on non-essentials."

rity of speech, of thought, and of writing is alto be desired. If the word "values" conveys to ader a more distinct idea than does another word, et us forget our feelings. If some other word is , let us use it. Meanwhile we may note that no ent substitute has been suggested. Not even The g Magazine can offer a practicable synonym.

s dangerous to carry very far the law of analoThe Mining Magazine objects incidentally to the phenated "footwall,' and takes as the ground of gument the antithetical term "hanging wall," is always hyphenless. What, then, can be said word "football"? Not even the hypercritical g Magazine would care to spell the word with an hyphen. Yet "foot-wall" and "football" are as closely analogous as words can be.

An end to this hair-splitting! It is well to be precise, exact, and accurate. It is not well to mistake the shadow for the substance.

FEDERAL MINING LAW.

Only a few mining men are aware of the debt of gratitude that the mining industry owes to the officers of the Canadian Mining Institute and to the committee, ably presided over by Mr. G. G. S. Lindsey, which is now urging the codifying by statute of the Dominion Mining Laws and Regulations.

Considerable progress has been made, and it is still hoped that a statute may be passed during the present session of the Dominion Parliament. If a statute is not passed, there will be compensation in the fact that the clauses of the Act will receive maturer consideration before becoming law.

The argument in favour of immediate action is extremely cogent. It is to be hoped that, before this session ends, the rights of mining men may be governed by laws enacted by Parliament, and no longer by Order in Council, or Regulations, or the arbitrary whims of the Minister of the Interior.

PLATINUM PRICES.

The prices of platinum are soaring. Recently, hard platinum reached the record price per ounce of $43, whilst the soft metal touched $41. Six years ago the pure metal was selling at $18.50 per ounce. Through the year 1906 the price of hard went up to $40. The market now declined until in August, 1908, prices had fallen to $20. Soon after this the rise commenced and has continued until the present. Within the last six months the advance has been most pronounced, amounting to practically $10.

One incidental cause of enhanced prices is the growing use of platinum in manufacturing jewelry. Another is the demand for the metal in making tips for the sparking plugs of automobiles. But probably the main factor is the closer control of the principal Russian sources of supply.

EDITORIAL NOTES.

In the course of a paper read by Mr. W. H. Prest, before the Mining Society of Nova Scotia, is given a list of 35 gold veins that have been opened in the province but on which little or no work has been done. In thickness these veins range from one inch to 2½ feet. Some of the smallest veins have been found to

be enormously rich. All of the veins mentioned have yielded assays exceeding one ounce of gold per ton.

Rarely has the weather of April been so excessively cold. In the northern mining camps travel over the ice was possible until well on in April. In eastern Canada the weather has been more severe than it has been for many years.

The appointment of Mr. R. B. Watson to the directorial board of La Rose Consolidated will meet with warm approval. The more voice given to technical men of Mr. Watson's type on the governance of large mining corporations, the better it will be for all concerned.

The U. M. W. A. leaders have taken a strategic advantage of the western coal operators by applying to the Department of Labour for a conciliation board. The two representatives appointed by the Department could not agree upon a chairman. The Department, therefore, has taken matters in its own hands and has requested the Rev. C. W. Gordon, otherwise known to fame as Ralph Connor, to act as chairman. May we express the hope that Providence is giving Mr. Gordon an excellent chance to make amends for some of his recent novels.

PYRITE PRODUCTION IN THE UNITED STATES.

Mr. W. C. Phalen, in his remarks about pyrite mining in an advance chapter of the annual report of the U. S. Geological Survey, alludes to the fact that the tremendous production of sulphuric acid at Ducktown, Tennessee, has not injured the pyrite business.

The United States production of pyrite in 1909 was 247,070 long tons, valued at $1,028,184. Whilst this is an increase over the output of 1908, it is just about equal to that of 1907. It is worth noting that thirty years ago the quantity mined annually in the United States was less than 30,000 tons. The State of Virginia produces almost 50 per cent. of the total annual tonnage. California comes next with 50,000 tons. The balance is distributed between Alabama, Georgia, Massachusetts, New York, and from a few other states. The average reported price was higher in 1909 than before. It was $4.16 per ton.

PYRITE MINING IN VIRGINIA.

For 22 years the Cabin Branch pyrite mine, near Dumfries, Prince William County, Virginia, has been in operation. The ore is iron pyrite carrying rich streaks of chalcopyrite. The ore body ranges from 6 to 14 feet in thickness and dips 45 deg. to 60 deg., striking northeast and southwest. A single compartment shaft is sunk in the ore. This shaft is down 1,500 feet.

In mining, drifts are run from the shaft in either direction to the end of the ore body at intervals of 100 feet or less. A raise is then driven from the end of each drift to the level above, if it has not caved. If the ground about is treacherous, from 2 to 6 feet of ore is left as a pillar. The pillar is kept as slight as possible. The raise is run about 20 feet wide. After opening up the raise a modified system of retreat longwall mining is carried on. Beginning at the end of the drift the ore is mined back to within about 30 feet of the shaft in successive strips across the end of the stope from the drift below to the pillar above. One 4-foot to 5-foot hole loaded lightly with 40 per cent. dynamite breaks the ore from foot to hanging. The ore is mined by contract. Drill-runners, working two men to the drill, using light tripod machines and furnishing their own powder, caps, and light, can make good living wages breaking the ore at 20 cents per ton. About nine-tenths of the ore is recovered.

There are now no less than five branch banks in Porcupine. That should be enough to accommodate even a boom camp.

Electrical power is to be generated at certain oil-fields in California and transmitted long distances for industrial purposes.

Had the birth of such gold-mining districts as those on the Lake of the Woods, Ont., been postponed ten or fifteen years, it is highly probable that they would now be figuring prominently on our stock exchanges.

For packing and transporting ore samples carefully made leather bags, construeted like large flour-sacks, and fitted with strong locking devices, are by far the safest. While these bags are costly, they last for a long time.

The British producers of aluminium no longer attempt to maintain high prices on a limited output. The combine went to pieces in 1908. Since then the policy has been to produce large quantities and to sell at moderate prices.

Within certain limits the freezing process is useful in sinking shafts in wet ground. But at great depths freezing is impracticable. Various other causes may militate against freezing. The process of injecting cement into the crevices that make the water is often the best means of checking the water.

Cable reports have it that the new Bewick-Moreing flotation in London will be called the Ontario Porcupine Goldfields Development Company. The capitalization is to be £600,000. The chief purpose of the flotation is to acquire 50 claims in Porcupine. It is the scheme is primarily to sell an option on undeveloped prospects.

The failure to produce peat commercially in the United States is officially attributed to overenthusiasm, lack of technical knowledge, too little capital and too much confidence in poorly designed and untried machinery. Both the peat in itself and the market are known to be alright. The total production of peat fuel is about 1,200 tons, valued at between $3.50 and $5 per ton. Unreported quantities of peat are used for such purposes as stable-litter, absorbents and fertilizers. Much of this material was imported

CORRESPONDENCE.

Editor, CANADIAN MINING JOURNAL:—

Sir,—Your Nova Scotia correspondent has, on several occasions, made mention of the services rendered by Draeger apparatus in connection with the fire in the Albion mines of the Acadia Coal Company, March-April, 1910.

In your last issue, he quotes the report of Mr. Thomas Blackwood, Deputy Mine Inspector, as taken from the 1910 Report of the Department of Mines of Nova Scotia, wherein it would appear that all credit for saving this mine was due to the men and apparatus from Cape Breton. The facts do not warrant any such credit being given or claimed from the standpoint of services rendered either by these men or the apparatus. To all those who know the conditions and circumstances in connection with the fire, such claims are ridiculously absurd. The use of rescue apparatus (whether Draeger or other types) so far meets with approval that a station is now being equipped by the Acadia Coal Company; but after our experience with them at this fire we are fully assured that their uses are strictly limited. This fact was made manifest to every one who had anything to do with them at this fire.

The location of this fire and the conditions of ventilation, water supply, relation of pillar workings to seat of fire, mode of attack, provision for safety of men at seat of fire and total absence of fire damp in the district affected, if fully described, would refute these erect-claiming reports in the minds of all practical mining men. But the writer has neither the time nor the inclination to give an extended description of the above.

Briefly, the facts are as follows:—On the morning of the 5th of March, 1910, it appeared that the fire might pass a certain point where every effort was being made to hold it in check; and as men engaged at the fire were working in noxious gases, or were obliged to pass through fumes in order to reach this point, it was decided to request the Dominion Coal Company and the Nova Scotia Steel & Coal Company to send men and apparatus, and every credit is given to both companies and men for their prompt response. In the meantime a way was cleared over a heavy roof fall for the men engaged at the fire to reach same without having to go through the return air from the fire. From 2 p.m. to 5 p.m., March 15th, was the crucial time if there was any danger of losing the mine, which none of those having years of experience in like cases either admitted then or will now. A shift of men from the Allan shaft, headed by Mr. Simon Lott, came on duty at 2 p.m. and if credit is to be given to any one or to any number of men, the full credit belongs to this shift. Either of the other two shifts would have done precisely the same had they been on duty during this time. At 5 p.m. the fire was so far under control that changes in water supply were started to increase efficiency and insure a steady supply when needed, so that nothing was done in actual fire fighting from this time until after the arrival of men and apparatus from Cape Breton. On their arrival at the scene of the fire between 1 and 2 a.m. on the 16th, the connection over the roof fall had been completed and water supply was ready to be turned on. All hands approached the actual fire *without* apparatus, and, in fact, the first stream was turned on the fire by Mr. John W. Johnson, Mine Manager of the Nova Scotia Steel & Coal Company, who had kindly come on from Halifax to render any assistance in his power. As a matter of fact, the fire was considered so far under control, and the means of fighting were so complete, that the services of Cape Breton men were not required. This pertains to all but two—one from the Dominion Coal Company, the other from the Nova Scotia Steel & Coal Company, who were retained for some time. These men admitted to the writer, not once but several times, that the Draeger apparatus was of practically no use in the existing conditions other than to make the briefest examination a short distance ahead of the men (without apparatus) working at the fire. As we *actually loaded all the material out of the seat of the fire*, wetting with water as we proceeded, it can readily be understood by mining men that, unless it is for advertising purposes, there has been neither warrant nor occasion for the "full meed of credit" given and so unctuously taken. As stated above, the full credit belongs to our own employees. The writer's opinion, from long and varied experience in mine fires, is confirmed by officials and workmen in the Stellarton field, who, from boyhood up, have had to contend with mine fires—that too much may not be expected from rescue equipment.

Yours, etc.,
CHARLES J. COLL,
General Manager.

BOOK REVIEWS

TABLES FOR THE DETERMINATION OF MINERALS BY MEANS OF THEIR PHYSICAL PROPERTIES, OCCURRENCES, AND ASSOCIATES — BY EDWARD HENRY KRAUS, PH.D., AND WALTER FRED HUNT, A.M.—254 PAGES — PRICE, $2 NET—MCGRAW-HILL BOOK COMPANY, 239 WEST 39TH STREET, NEW YORK, 1911.

The mineralogical tables that make up the bulk of this book are based mainly upon lustre and colour, streak and hardness being subsidiary. Two hundred and fifty of the most common minerals are classified into three groups—those that are very common, those that are common, and those that are not common but are important. The very common names appear in black capitals; the common, in light capitals; and the third group in lower case type.

In the introduction, the physical properties of minerals are very briefly outlined. Then follows an adequate glossary. Then come nearly 240 pages of tables. tables.

Minerals with metallic lustre are dealt with in the first 67 pages. The colour sequence is thus arranged: dark gray or black; metallic white or light metallic gray; yellow; brass, bronze, or copper red; red, brown, or blue. To each colour several successive double pages are devoted. The horizontal headings are so devised that one sees at a glance the name, composition, crystallization, structure, lustre, colour, hardness, streak, cleavage, fracture, tenacity, specific gravity, characteristics, and associates of any given mineral. In the first column are included page references to the textbooks of Kraus, Dana, and Moses and Parsons. The remaining 179 pages are tables of minerals with non-metallic lustre, done in the same style as indicated.

We are decidedly impressed with the simplicity of the plan followed in designing these tables. The book is so clear and places so much proper stress upon the most immediately available means of distinguishing the different species, that it is bound to prove acceptable.

THE QUARRYING OF ASBESTOS

Notes from Chapter three of the monograph "Chrysotile-Asbestos."*

The work of extracting the asbestos from the rock in which it occurs, and converting it into a saleable article, will be described under the following heads:

(1) The quarrying proper, that is, the blasting, separating the dead from the useful material, hoisting the same from the pits, and transporting it to the cobbing sheds or mills.

(2) The cobbing or dressing of the better qualities, that is, the separation of the fibre by hand from the adhering rock particles; together with the mechanical treatment, in mills, of all rock or fine material containing fibre; grading of products; and subsequent transportation of product over railways, and by shipping to the markets of the world.

It is important that all the different stages through which asbestos has to pass until it is a finished product, be treated separately; since these involve the entire expenditure from the winning of the crude material in the rock, up to final delivery to the consumer.

ADVANTAGES AND DISADVANTAGES OF OPEN-CAST WORK.

Nearly all the companies employ the method of open-cast work as the means for exploitation of asbestos deposits; for in spite of all its disadvantages—especially in severe winter weather—it has proved itself to be the most convenient and the cheapest method hitherto employed. Its advantages over underground work may be summarized thus:—

(1) Easier supervision.

(2) No trouble as regards ventilation the men are always working in the open air.

(3) Easier lay out of works in larger steps and stopes than is usually possible in underground works.

(4) No timbering is necessary.

(5) Complete extraction of all the asbestos encountered in the rock; no loss in the form of pillars.

The principal disadvantages of open-cast work are:

(1) The removal of all the waste rock resulting from dikes and barren zones of serpentine.

(2) Exposure of men to the inclemency of the weather: work is interfered with; amount of work done reduced considerably; or even stopped by bad weather.

(3) Curtailment of dumping ground on properties of limited extent.

However, recent experience in a prominent quarry at Thetford seems to demonstrate that open-cast work, under certain conditions, may be replaced by regular underground methods; and although all the difficulties in connection with their general application—such as we are accustomed to find in lode mining—are not wholly overcome, it seems reasonable to assume, that before long, the larger and richer mines, at least, may follow suit.

The question of underground mining has been taken up spasmodically by different companies in the district. At the "Union" quarry, some twenty years ago, a somewhat extensive tunnel was run during the winter from the foot of a hill and a shaft sunk in connection with it; but the results are not definitely known. In the old Broughton (Fraser) mine a shaft was sunk to a depth of 100 feet along an excellent bestos vein near the contact with the slate format and it is reported that the results were satisfact for the first 75 feet; but owing to the irregular cl acter of the vein below that depth, work had to abandoned. Seven years ago, the Bell Asbestos C pany, sunk at Thetford, a roomy shaft in the west part of the property close to the King quarry; this experiment was not successful, since the sl went through an apparently barren zone, and li hope was entertained as to finding better conditi in the immediate environment.

For a long time after this experience, undergro work was looked upon in the district as an im sibility It was affirmed in support of this conten that the asbestos pay shoots were distributed i very irregular fashion; indeed so irregularly that economic system could be brought into operation; moreover, that due to this cause also, valuable gro or perhaps pillars composed entirely of valuable posits, would have to be sacrificed for the sake safety. It was further maintained, that on accoun the highly slippery condition of the serpentine, narrow drifts could be run; otherwise a great amo of timber would be necessitated in order to sup the ground so penetrated, and that, in consequenc this, the cost of extraction per ton of ore would excessive. The underground work, however, i gurated and successfully carried on by Mr. Geo Smith, M.E., at the Bell quarries, seems to demonst that not all of the contentions hitherto brought ward can be substantiated; indeed it has been sho that after all not so much timber is used, in spit the fact that all the drifts are very large, much l er than in any other class of underground min Further, the question of valuable pillars for the pose of safety may be regulated to satisfaction, s the running of a system of approximately par drifts in different levels, admits of a thorough stud the ground preparatory to the winning of the min proper. As to the employment of timber in the dr it may here be stated, that the total length of un ground work in the mines of the Bell Asbestos C pany, is now 1½ miles, and the writer, who inspe these drifts twice, noticed very little in any of t No accidents caused by a falling roof have occu so far, for a rigid inspection is made almost dail the workings. With increasing depth, however, ditions in that direction will probably materi change; the rock pressure will increase, necessitat perhaps, heavy timbering, where to-day nothing the kind is required.

The great advantage of this mining method quarry work is the convenience with which the w can be carried on during the winter. In open wo to win the asbestos through ice and snow, and s times very cold weather, reduces enormously the w ing results; the drying of the ore, which is m most of the time with snow and ice, requires al three times the amount of fuel needed at ordi times; while the transmission of compressed air, more especially steam, to the pit bottom, has its g difficulties. For this reason it is questionable whe

*Chrysotile-Asbestos, its occurrence, milling and uses; by Fritz Cirkel; issued by the Mines Branch, Ottawa.

days at all to work some of the quarries in severe winter season. As a matter of fact, if prices are not specially tempting, a number of them close down altogether.

One of the greatest hindrances in the way of economic open quarry work is the selection of a suitable dumping ground. Many mines which have little ground at their disposal, find considerable difficulty in solving this problem. In the early days of asbestos quarrying, when very little engineering skill was displayed, and little thought was given to projected efficiency, most of the dumps were placed quite close to the quarry, as was the case in most instances. This accumulated waste rock had to be removed, when it was found that the ground so covered contained large asbestos-bearing zones. To-day — in some of the quarries on ground specially bought for that purpose — long, horizontal, gravity tramways are built to remove the dumps as far away as possible.

The question of the disposition of the dumps is daily becoming of increasing importance; in fact some of the companies that formerly treated this subject as a secondary matter are beginning to give it earnest attention.

In underground mining excellent facilities for the placing of dead rock are afforded; since a system similar to the methods employed in wide lode mining may be introduced, whereby stopes can be filled conveniently with the debris. This would also secure safety against unexpected cave-ins, and would, in addition, greatly increase the general working economy of the mine.

However, taking into consideration all the advantages of both methods, together with their disadvantages, it must be said that the open quarry method remains the favourite of the miner, and will, doubtless, be retained as long as circumstances permit. Moreover, there seems to be no doubt that the application of the underground method — as introduced by Mr. Geo. Smith — will be confined only to such mines as work on approved rich ground, and the practical working sphere of which permits of gradual expansion. It will thus be seen, that in future the probability is, that the richer mines may employ the combined quarry and underground method: the one preferably for the summer season, and the other for the winter.

Removal of Overburden.

The first operation in opening a quarry is the removal of the soil which covers most of the asbestos-bearing areas, which varies in thickness from a few feet up to 25 feet. In Black Lake, the crest and slope of the large serpentine ridge is for the greater part covered with a thin layer of humus, thus rendering prospecting work comparatively easy; the lower ground of this locality, however—the area between Black Lake and Thetford—is covered to considerable depth with soil, while at Thetford, the thickness of the overlying soil is, in some places, 15 to 20 feet. The removal of this soil for open quarry work is performed only in the summer time; the winter, on account of frost and snow, being too severe for this class of work.

The soil is generally cleared off with pick and shovel, and loaded into large dumping cars on trucks which are laid for this special purpose close to the work, and lifted when required.

Several of the larger Thetford companies employ steam shovels for this purpose.

Quarry Work.

As a rule the quarries in the smaller mines have a very irregular shape: most of them following the trend of the asbestos-bearing zones; while the lean serpentine, or intrusive dikes, are left as pillars. In the larger mines, however, where the locations of the asbestos-bearing and lean rock, and the location and extent of intrusive dikes have for years been more fully studied, the quarries have, generally, a more regular outline: as at the King and Bell pits, Thetford; also at the large quarry in Danville.

At these quarries, no discrimination has been made between dikes, lean or rich portions of the serpentine; no pillars of any rock have been left, for the reason that these would only prevent mining with advantage towards depth. The shape of the quarries is rectangular: and while the outlines of the walls are not strictly in conformity with that shape, nevertheless the execution and the progress of the work in the pits indicates that a definite system has been followed in late years. The principal advantage of the system employed in these mines lies in the fact that, generally, a number of different zones—both lean and asbestos-bearing—are thus laid open, hence the work, also the supply of ore, can be regulated to better advantage according to requirements.

As a general rule, in all the larger pits the rock is taken down in a series of benches, stopes, and terraces, which vary in dimensions according to the size of each pit. A good illustration of systematic progress in quarry work is the long pit of the King quarry of the "Amalgamated Asbestos Corporation," at Thetford. This pit has a length of 1,350 feet, and an approximate average width of 350 feet. The height of the benches and stopes varies from 5 to 30 and 40 feet in the deepest part; while the length of the terraces varies between 50 and 250 feet.

Explosives.

The great bulk of the dynamite used in the asbestos quarries contains 40 per cent. of nitroglycerine; the cartridges being, as a rule, 8 inches long, by 1¼ inches diameter, and are packed in boxes of 50 pounds, containing from 85 to 95 cartridges. The price is from 14 to 15 cents per pound.

Effect and Cost of Hand-drilling.

Hand-drilling is still in use in the smaller quarries and prospects, also for block-holing.

As a rule, three men are employed with 1-inch octagonal steel, and six or seven pound hammers. The average capacity in hard serpentine or granite is from 15 to 18 feet per shift; and the cost per foot—including explosives—from 24 to 28 cents. In some of the mines block-holing is done by one man only; using ¾-inch steel, and three to four pound, short handled hammers. The capacity is from 7 to 9 feet per day, and the cost — including explosives — about 20 cents per foot.

Effect and Cost of Machine-drilling.

In nearly all the quarries, machine-drilling is in vogue for the breaking of the rock in situ. The proper placing of the holes is a very important factor in obtaining the best results from blasting in asbestos rock. It is necessary that the operator have a thorough knowledge of the position of the strata, and the position and trend of cracks and fissures. To obtain

this knowledge, the intelligent miner examines the rock attentively, and carefully ascertains for each blast the position of any joints and fissures in the rock; to enable him to form a judgment as to the proper direction to be given to the hole, and the free sides available for the best results; but it happens, too often, that two miners will have different opinions as to the proper charge for a certain shot. The result is, very frequently, a waste of explosives, which sometimes assumes considerable proportions. Where the rock is massive, and the walls of the benches to be taken down vertical, the direction of the holes is vertical, or nearly so; and when the rock is much fissured, the holes have, generally, an inclined position according to the largest fissures and the bulk of the rock to be taken down.

When blasting benches having several free sides, the holes are arranged in rows, and they are as nearly as possible parallel with the largest free side, so as to obtain the deepest hole, and thus be able to use, relatively, the smallest quantity of explosives. In order that the charge may be as fully utilized as possible, due regard is given to the contour of the free sides and the longest line of resistance. The holes in this case are generally made vertical, so that the explosion will not have to lift the rock it breaks down, but will allow it to fall by itself, and thus gives less work afterwards in removing.

The depth of holes ranges between 8 and 10 feet, and in the case of exceptionally large faces, 12 and 15 feet. The charges of the drill holes vary, of course, according to the position of the latter, quality and quantity of rock as outlined above; but, as a general rule, in the course of ordinary work—where the faces are free on one side—from 0.45 to 0.5 pound of dynamite is used for every foot drilled.

The rock drills in use are mostly of the Ingersoll and Rand types, with 3⅛-inch cylinder, and a stroke of 6¾ inches.

Electric Drills.

Lately, electric percussion drills have come into use; but many improvements will have to be made on the present design before their use will become general. Most of the manufacturers have adopted the following method: power is conveyed from an electric motor—which is placed either on the drill carriage, or in a box lying on the floor—to the drill by a flexible shaft. Compression springs are placed in the rear of the carriage; the drill carriage being released when the springs have been compressed to a certain pressure, and the drill is thrown forward by the force of the expanding springs. There are springs in front of the carriage also, which force the drill back after the blow has been struck; and there is the usual shifting arrangement, which comes into operation as the drill returns; by means of which, rotation is effected. In another form of drill—known as the box drill—air is compressed inside a cylinder forming the drill carriage; the drill being held in front and working in guides as usual, while the compression of the air is accomplished by an electric motor attached to the back of the drill.

In another percussion drill the following principle has been introduced: motion is communicated to the drill by means of a solid plunger, around which two coils of wire are fixed; electric currents passing into one coil, which, in receding, compresses a strong spiral spring in the rear. It is forced forward by the current in the other coil, aided by the force of the expanding spiral spring.

Electric drills in the asbestos quarries have several advantages over those actuated by steam or compressed air, especially in the winter time; since there is no loss through transmission, and the working effects are generally much higher.

For block-holing, little giant drills are used: the diameter of the piston is only 1⅞-inch, length of stroke 3⅝-inch, and depth of holes drilled from 1 to 2 feet.

The steel usually employed is octagonal in shape 1⅛-inch in diameter for the larger, and ⅝-inch for the smaller drills.

The motive power for actuating rock drills is usually compressed air, or steam; but in utilizing the latter, there is a large loss from condensation in transmitting steam from boilers to the drills: especially in the usually severe winter seasons, when all the main pipes require to be covered with insulating material which entails extra cost.

Compressed air has a great advantage over steam the loss in transmission is small, hence the amount of drilling done is comparatively high. The operating results with steam drills are from 40 to 45 feet, per shift of ten hours. The total cost per foot—including power, labour, and explosives, at present prices of fuel—is from 15 to 18 cents; not including, however, wear and tear of machinery and interest on capital involved.

In nearly all the quarries the firing of shots is performed by means of electric batteries. There are few instances where one-hole blasting is still in vogue. In support of this practice it is urged that not alone is a saving of explosives effected, but that the expense of picking them up is less; because the asbestos veins are less liable to be smashed to small fragments, and widely scattered.

The expenditure for explosives per ton of rock broken, in mines where the rock is of a solid, massive character, is 3 4/5 cents per ton; in mines where the rock is much fissured and shattered, as in the East Broughton mines, the cost is a little less.

Each pound of dynamite brings down, on the average, 4.25 to 5 tons of rock.

Separation and Removal of Rock and Ore.

After the firing of shots, the broken material undergoes a hand-sorting process; which is different in every quarry, according to the grades to be produced and the ground worked. Where no crude or hand cobbed fibre is produced, all the rock containing fibre together with the fines scattered all over the pit, is sent to the mill; but in quarries where the different qualities of crude are produced, the material to be treated comprises:

(1) The long asbestos fibre, and pieces of rock containing the same.

(2) The milling material, or rock, containing the shorter fibre.

(3) Fine material, and the scrapings of the pit resulting from blasting and breaking up the rock by means of sledge hammers.

(4) Dead rock.

The material specified in No. 1 is sent to the cobbing sheds, and the material indicated in Nos. 2 and 3 is sent to the mill: the fines going first, however, to the dryer.

If the bottom of the quarry is on the same level as the top of the dump, the removal of the debris is simple: the latter is loaded directly into dumping cars or on a platform, and subsequently placed, by means

small derrick, on trucks, and then delivered to destination; but in most cases where deep mining going on heavy boom and cable derricks are employed.

Construction of Boom Derricks.

Boom derricks are employed in only a few of the smaller mines, or where dumps have to be worked over again. Quarries of large dimensions do not, generally admit of the successful application of boom derricks; on account of their very limited working radius.

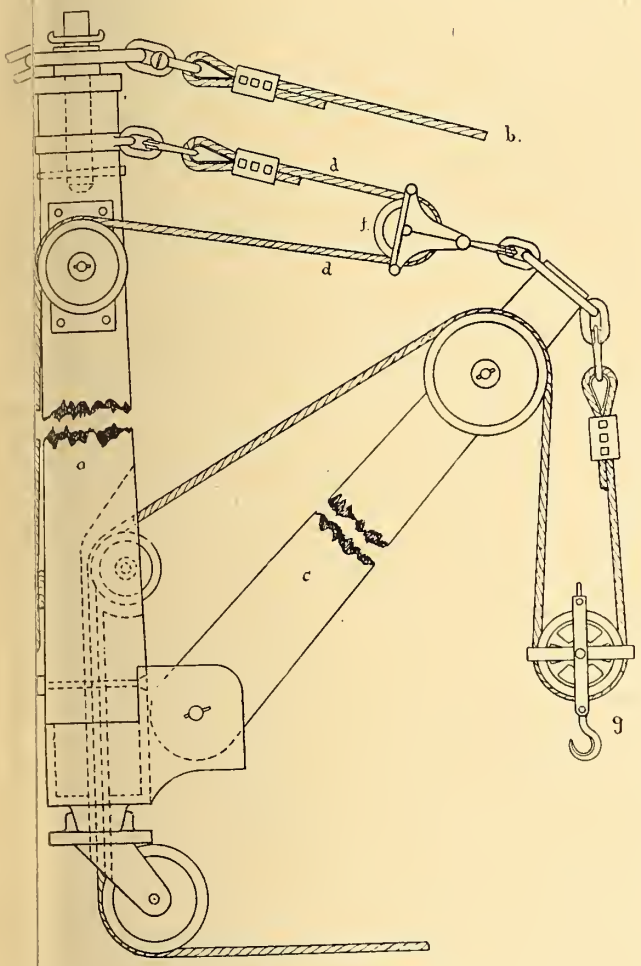

Fig. 19—Boom derrick.

A boom derrick (fig. 19) consists of a mast held in a vertical position by means of guy ropes or legs. To provide for the rotation of the mast about its vertical axis the lower end of it is pivoted into a socket of the fixed bed-plate. A boom or arm is hinged to the foot of the mast immediately above the pivot. The farther end of the boom, which carries the load, is suspended from the top of the mast by ropes, which pass over pulleys to permit the variation of the inclination of the boom to the mast. The length of the boom is from 30 to 50 feet; its working radius is naturally limited and can hardly be extended more than 50 feet.

Construction of Cable Derricks.

A cable stretched from the top of a well guyed frame or mast to some point across the working pit, along which the load is to be transferred, constitutes the main feature upon which the cable-derrick is constructed. A carrier suspended from the cable by a system of pulleys travels along the cable, and may be arrested, lowered to pick up the load, and rehoisted at any point between the limits of the cable.

The cables may span a distance of 400 feet, are made of crucible steel, and are from 1½-inch to 2-inch diameter: depending on the length of the span and load to be carried. The ropes for hoisting are from ⅝-inch to ¾-inch diameter.

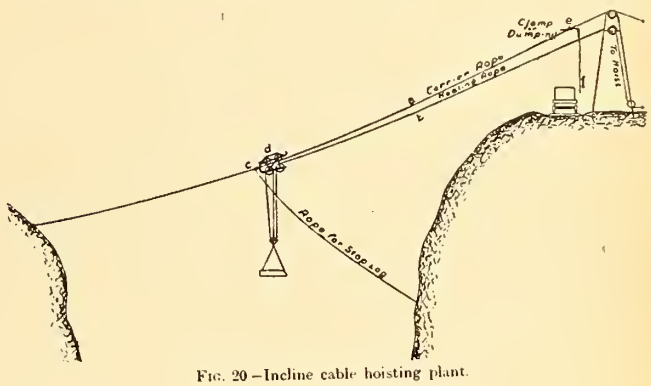

Fig. 20—Incline cable hoisting plant.

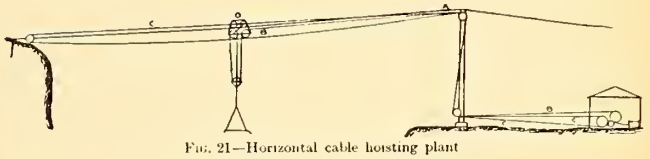

Fig. 21—Horizontal cable hoisting plant

The cable ways may be either inclined (Fig. 20) or horizontal (Fig. 21).

The cable ways may be either inclined (fig. 20) or horizontal (fig. 21). In the case of the inclined cable way the carrier is provided usually with one rope: the fall rope, which is also used as a hauling rope. To prevent the carrier moving along the cable when the load is raised, it is necessary that the angle of inclination of the cable be at least 30 degrees, to render the component of the force of gravity of the load acting down the cable of sufficient intensity to retain the carriage in position until the load arrives at the stop on the cable.

On stopping the carriage at any point on its upward journey, the load may be lowered and dumped, after which the carriage returns down the incline to the stop. It is generally necessary, however, to provide a bridle or link (e), pivoted to a wooden clamp on the carrier rope over the dumping point, which link is raised by a cord, (f), and dropped over the hook on the end of the carriage before dumping, and afterwards released to allow the carriage to return.

To obtain control of the carriage so that a load may be picked up or lowered at any point on the line, without shifting the stops on the carrier rope, a third rope or extra hauling or tail rope, ⅜-inch diameter, is required; which is attached to the carriage and wound in at the same speed as the fall rope after the load has been lifted, and by means of which the carriage may be restrained in its movement down the incline on the return trip, or made to stop over any point in its range of travel for loading or unloading purposes.

By making the hauling rope endless · that is, by passing it from the carriage around the separate winding drum on the hoist and around a sheave on the farthest end of the cable way, the latter may be used in a horizontal, instead of inclined position. In some quarries the inclined, and in others, horizontal cable-

ways, with tail rope are utilized. Miners generally prefer the horizontal to the inclined cable-ways, on account of the ease with which the carriage may be stopped at any desired point from the hoist; while with the inclined cable-way a constant shifting of the stopping log on the cable rope is necessary.

The support for the cable consists either of a pyramid, constructed of four legs fitted and bolted seeurely; or of two legs held in vertical position by 7/8-inch guy ropes arranged in the manner illustrated in

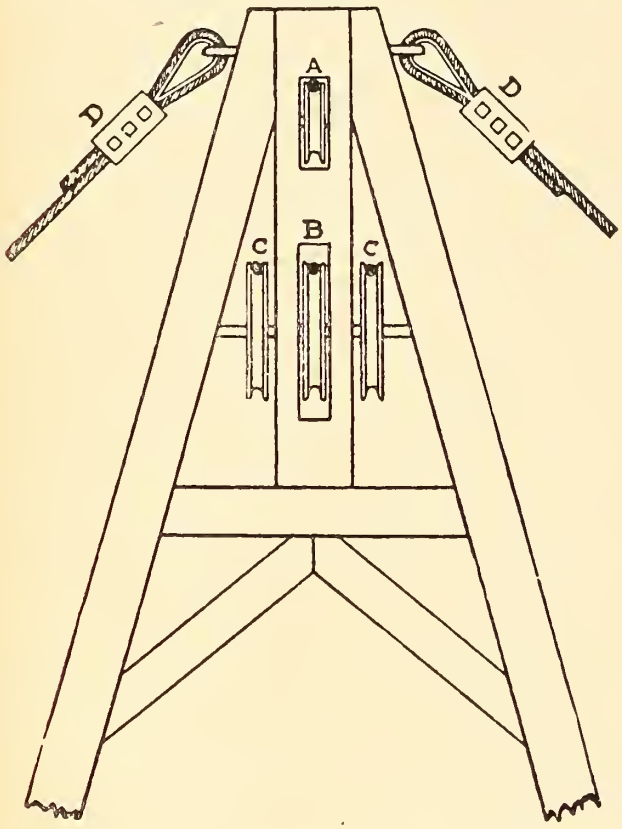

FIG. 22.—Two-leg support for cable derrick.

(A) Carrier rope. (C) Hauling ropes.
(B) Lifting rope. (D) Guy ropes.

fig. 22. On the top of these supports are placed the sheaves for the carrier and haul rope. It is claimed for the pyramid-shaped supports that they are very rigid, and strong, and do not require any guy ropes; while the two leg supports are of simpler construetion and can be more easily removed.

Single mast supports were perceived in one mine; but they are exceptions to the general rule.

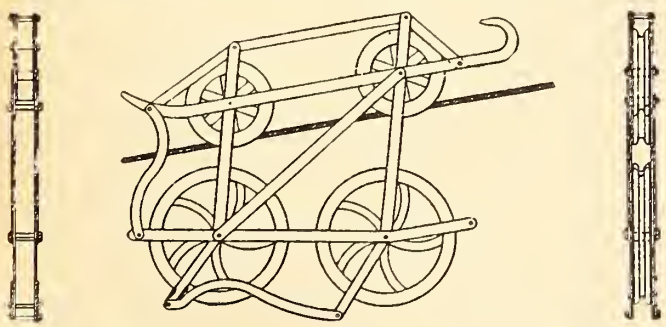

FIG. 23.—Carrier for cable hoisting.

The eable carriage (fig. 23) is substantially con structed of wrought iron, and is yet comparatively light. The running wheels are of cast iron, hav flanges, and, as a rule, are provided with anti-friction bearings. The hoisting wheels are of cast iron, 1 inch to 24-inch diameter, in order to reduce the wea on the hoisting rope, and to enable the gin block t lower as freely as possible.

The boxes for hoisting are made of 2-inch hardwood and hold, generally, from 16 to 20 cubic feet o rock, weighing from 2,200 to 2,500 pounds. The bo tom is covered with 1/4-inch steel plate; while in som quarries the outside corners are covered and protec

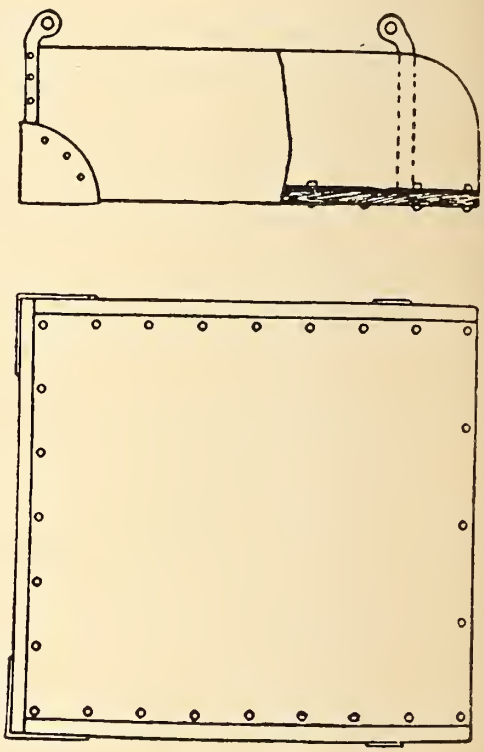

FIG. 24.—Construction of transport boxes

ed by heavy flanges (fig. 24). It is claimed that a bo of the above construction in ordinary work does n last longer than from six to eight months. One com pany has attempted to use boxes made of iron; but appears that the experiment was not successful.

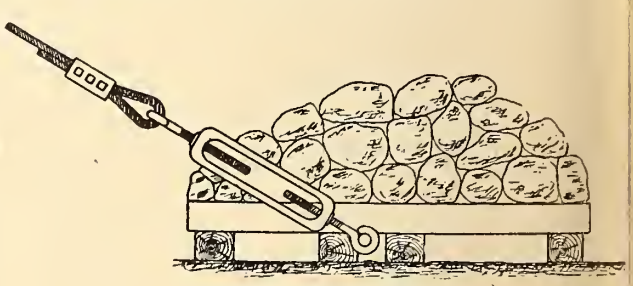

FIG. 25.—Anchorage of carrier rope.

The heavy cable is fastened at both ends, either a system of heavy wooden legs loaded with ston (fig. 25), or to a large iron bar securely fastened in drill hole in the solid rock.

For the purpose of stretching the cable from tim to time, a turnbuckle is inserted at one end of t cable, in the manner illustrated in fig. 25

Hoisting Engines.

All hoists used in the district are of the double cylinder type, with reversible friction drums.

Efficiency of Hoisting Plants.

The number of tons of rock which can be raised from a quarry by means of a cable derrick depends upon the depth of the pit, the distance to be hauled, and the capacity of the machinery. As a rule, however, the distance in nearly all the quarries does not exceed 400 feet; while the greatest depth so far attained is 185 feet. Taking these figures as a basis, and assuming the load to be one ton, and the capacity of the hoist 40 horse-power, an average of from 240 to 300 tons can be raised in a ten-hour shift. It must be understood though, that a cable derrick is used also for other purposes: for instance, the lifting and shifting of heavy pieces of rock in the quarry in order to clear the working face after blasting. On account of the work entailed through the separation of the useful from the dead material in the bottom of the pit, a cable derrick is very seldom used to its full capacity. In order, therefore, to provide for a steady supply of ore in all the quarries, a larger number of such mechanism as will permit the tilting of the box to both sides of the track.

The gauge of the latter is 42 inches. In all the larger quarries haulage is being done by small 10 and 12-ton locomotives; and it is claimed that not only is the cost of transport per ton considerably reduced, but that accidents are very few. The first introduction of these small locomotives was made by Mr. Geo. Smith, in 1895, who used in their construction two cylinders from an old hoisting engine, in connection with gearing motion.

The steel rails employed are of either 19 pounds to the yard, for light dumping cars; or 45 pounds, for mechanical haulage.

General Hoisting and Hauling Arrangement and Position of Cable Derricks.

The position of the cable derricks is determined by the location and number of working points in the pit, and changes with the shifting of operations. Where the quarry is of rectangular shape, all the supports and hoisting engines are, as a rule, placed on one side of the pit; the former usually all on one row near the border of the pit, leaving, however, enough space for the passage of dumping cars. A good illustration of

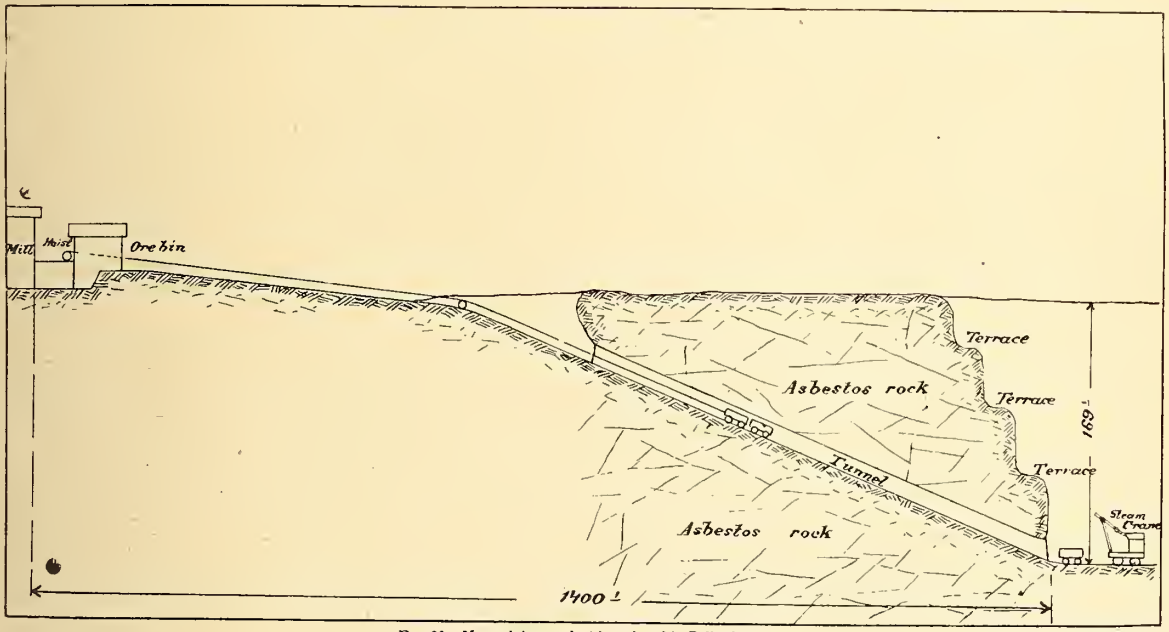

Fig. 26.—New mining method introduced in Bell mines.

cable derricks than the regular output capacity indicates, are employed and stationed along the quarries. In illustration of this, it may be cited that one company treating about 300 tons of asbestos rock in the mill and raising for this purpose as an average 500 tons, has employed eight cable derricks.

Haulage and Dumping.

The dumping cars in use are of two classes: (1) those hauled by men or by horses, and (2) those hauled by power. Dumping cars of the first class consist of a truck and a movable box, constructed for a 26-inch gauge, and holding from one-half to one ton.

The box cars for power haulage hold from three to six tons of rock. They are furnished with brakes and

this arrangement is the large "King" pit of the Amalgamated Asbestos Corporation at Thetford. The derricks employed here are all of the tail-rope type; the cables being stretched nearly parallel at fixed intervals over the pit; while all the hoists — some of them are grouped together in one building — are stationed back of the supports.

In cases where the pits have an irregular shape, and curved outline, an effort is generally made to place the hoists and supports on one central spot, from whence all the cable-ways can be operated.

The tracks for the haulage of dumping cars are generally laid alongside, and close to the borders of the quarries. Generally, two tracks are close to each other; one for the loaded and the other for the empty cars.

In some of the mines the tracks are of an ascending grade towards the pit; allowing the loaded cars to descend by gravity for some distance to a shunting yard, where they are sorted and delivered to their destination.

An ingenious device for the disposal of the mill rock from the pits, the only one of its kind in the district, has been installed at the quarries of the "Jacobs Asbestos Mining Company," of Thetford Here the boxes coming from the pits by way of cable derricks are dumped in a system of ore pockets which empty into a pan conveyor below. The latter transports the ore directly to the ore bin of the mill. There are altogether installed 7 cable derricks with as many ore pockets. The conveyor has a total length of 325 feet, and consists of heavy steel pans 30 inches wide, each pan being reinforced by angle iron. Its velocity is 40 feet per minute.

The signalling from the pits to the hoists in shallow workings is effected by shouting; but where the pits are deep, and where the operations cannot be noticed by the engineer, boys are stationed at points of vantage on the border of the pit, who convey the signals either by electric bells or by means of a galvanized wire to a hammer which strikes a bell, the number of strokes indicating what is required.

Each engineer stationed at a hoisting engine marks the number of box loads he has hoisted during the shift, and the summary report of all the hoisting engineers' records must tally with the number of cars delivered at the different stations; i.e., at the cobbing shed, the dryer, the mill, and the dumping ground.

Recent Improvements in Hoisting Appliances.

The suspended cable—which replaces the boom derrick in all cases where a wider range of operations is required—with its travelling, hoisting, and propelling lines, possesses many advantages. First of all, the main cable, suspended high over the quarry from the terminal towers, provides a roadway entirely independent of obstructions and of the condition of the surface. Having no other supports than those provided at the terminals, it has one clear span, hence there is no interference with the passage of trains, waggons, or other work carried on within the range. With a suitable equipment in the way of engine, sheaves, carriers, and skips, almost any kind of hoisting may be carried on with a certain amount of speed, and over a comparatively large range. It comes here in direct and successful competition with the boom derrick; for it does the same work with a substantial saving in operating expenses. Upon watching closely the operations of these cable derricks, however, we find that they also have their serious drawbacks; and this is more apparent the greater the quantity of low grade material handled. In order to work simultaneously at many points in a big quarry it is necessary to install quite a number of these cable-ways In one pit, measuring over 1,000 feet in length, twelve cableways are being operated, and this necessitates twelve different hoisting units; each consisting of cableway hoist, cable tower, two or three heavy cables, and other accessories. Moreover, the operating expenses; the permanent watch necessary to keep these units in good order to prevent any accident; the time lost by the men in the quarry—as is generally the case—in watching the arrival or departure of the hoisting skips; are all factors which, when considered in the proper light, tend to offset, to some extent, the apparent advantages that at first sight appear.

These negative facts are now recognized by engineers, hence efforts have already been made to do away, to a very large extent, with the cableways in cases where larger quantities of rock are to be handled and to substitute a tramway service instead — where the location of the quarry permits of such a course The "Bell" people, at Thetford, are the first to be credited with this innovation. When the present proprietors — Messrs. Keasbey & Mattison — took over the property several years ago, their manager, Mr. Geo. Smith, made a proposal to connect their great quarry with the mill: which was located at a distance of 1,100 feet, by rail through a tunnel, allowing at the same time a thorough exploration of a long stretch of virgin serpentine. This plan was at once accepted and executed, with the result that to-day all the rock instead of being hoisted by cable derricks, is hauled in large 5 ton cars over a tramway through a tunnel to the mill. The advantages of this hoisting system are manifest, and need no further comment. There are a number of quarries in the district, the location of which permits the introduction of a similar tramway service; and although the initial expenditure of making a tunnel or open-cut in connection with the tramway may be high, yet the operating expenses are so low, compared with that of ordinary cable derricks, that the money invested may be considered well spent.

Compressed Air.

In some of the larger mines the motive power for actuating rock drills and hoists is compressed air generally supplied by straight-line air compressors.

In order to secure uniformity of pressure, and to get rid of the water, and impurities, the air is led from the compressor into a receiver, which is generally supplied with a safety valve, and pressure gauge also a cock for letting off the water which gradually collects.

Where the distance of the pit from the air compressor is long—over 500 feet, a second receiver is installed about half way, for the purpose above indicated. The capacity of an air compressor is generally estimated by the number of rock drills it can supply There are 3, 7, 14, and 20 drill, air compressors, all which are employed in the asbestos region. The pressure usually produced for air drills is 80 pounds.

The straight-line air compressors which are extensively used in the district, have the great disadvantage of consuming too much steam. They are now being superseded by the duplex, compound steam-air compressors, which are constructed on more economic lines.

The annual analysis book of the Lake Superior Iron Ore Association has just been issued. The list of analyses includes 283 ores. Michipicoten and Sudbury Canadian ores are listed. The former are classified for the trade as "Algoma," "Helen No. 1," and "Helen No. 2." Of the various groups of the Steel Corporation's ores only two show increases in iron content. These increases are partly or wholly due to reduction of moisture content. The remaining ores fall off slightly in iron percentages.

In the oil fields of Galicia, Austria, there are now 135 producing wells, and 204 new wells are being drilled. The Austrian State Railways use oil exclusively. This provides a steady market.

A PERSONAL NARRATIVE OF THE BELLEVUE, ALBERTA, RESCUE PARTY.

The following narrative has been submitted to us by an official who took an active part in the efforts made to rescue the miners entombed in the Bellevue colliery after the explosion last December. The narrative and covering letter were written for the purpose of correcting a statement that appeared in the CANADIAN MINING JOURNAL, February 1st, 1911, to the effect that the Draeger apparatus installed at Hosmer, B.C., were of the 30-minute type.

Our correspondent shows that this statement was only partly correct.

The lessons learned by the Bellevue experience are numerous. Not least important is the demonstration of the mischievousness of official interference. The narrative should be read with close attention.

THE NARRATIVE.

On the 9th December, I was informed that there had been an explosion in the Bellevue mine of the West Canadian Collieries Company, Bellevue, Alberta, and that assistance had been requested. I was informed that there was a special train on the way from Fernie, to take the rescue party up to Bellevue, which is situated about 42 miles east of Hosmer.

After assembling a few men, we had three "Two-hour Type" Draeger apparatus, two "One-half-hour type," pulmotor, pump, spare cylinder of oxygen, and a supply of spare small cylinders for the "two-hour" type, with the necessary potash cartridges, packed up and put aboard the train. Accompanied by Mr. D. G. Wilson, manager Hosmer Mines; F. Alderson, fire-boss, Hosmer; and Mr. Fuller, secretary, we proceeded to Michel, where we picked up Messrs. Ashworth and Fraser, of the Crow's Nest Pass Coal Company. We arrived at Bellevue about 1.30 a.m., after having to change all our apparatus from one car into another at Coleman, causing a delay of about 20 minutes.

It was about 11.30 p.m. when we received word in Hosmer of the explosion. I decided to take only the three apparatus ("two-hour type") owing to Mr. Ashworth having informed me that we would not require them. As Mr. Ashworth had investigated an explosion in this mine about six weeks previously, he informed me that he was almost sure we would not require the rescue apparatus. We had the apparatus taken to the lamp room, where I left it in charge of Alderson while I proceeded to the office to see if any of the mine officials were there. Not finding any of the officials, I decided to go into the mine, and, taking the apparatus, we proceeded in a car for some distance. Then, owing to some coal having blocked the way, we had to walk. At about one mile and a half we found the rescue party bringing out the bodies of twenty-one miners who were found near a leak in the high pressure line. At this point I found Mr. Powell, the manager, and, after introducing myself to him, I suggested that he send out to the lamp-room for the doctor in whose charge I had left the pulmotor, as it might be useful to try it on these men. I might mention that I left the pulmotor in the charge of the doctor as he had been instructed to stay outside. I also showed him the way to use the pulmotor.

Mr. Powell then asked if we could explore the level, so Alderson and myself put on the Draeger apparatus and started in. We had only gone about 500 feet when Alderson complained of something being wrong with his apparatus and I had to assist him back to the starting point. On examination I found that the nipple connecting the oxygen cylinder and the apparatus was loose and all the oxygen had escaped. Here I may state that I had been away from Hosmer for three weeks taking in the Mine Rescue course at Seattle, and had only returned that night; therefore, to make sure, every part of the apparatus was examined in the presence of Alderson and Wilson on the road coming to Bellevue. After a short rest, Alderson requested to be allowed to put on the other apparatus, and as he appeared to be all right, I acceded. We proceeded in the level about 2,000 feet, where we found eight miners alive around the high pressure charging station. I explained to these men that we would return and get the two "half-hour" apparatus and take them out.

Starting out we had only gone twenty feet when Alderson stopped and informed me that he would give one of the men his apparatus so as to allow the miner to go out. This I protested against, and informed him that it was not right. Still Alderson insisted on going back, and took his apparatus off, giving it to one of the miners, who accompanied me out. On arriving at the starting point, I informed Mr. Powell of how things stood, and asked that men be sent out to bring in the two "half-hour" set, also a further supply of potash and the spare oxygen cylinders for the "two-hour" apparatus. I then returned inside, carrying Alderson's apparatus,. This he put on and I gave mine to another of the miners, who accompanied Alderson out. On Alderson returning inside, he was completely exhausted and had the chin valve of his apparatus open, but was able to inform me that he had dropped my apparatus on the road in; also he thought that in the one he had on the potash cartridge was done. Assisted by the miners, I took the apparatus off and put it on to try it, and found that it was all right. I started for the outside and you can judge that the entombed men were in good condition when two of them accompanied me out for 15 or 20 feet to see if I was all right. I arrived at our starting point, and urged that some person go out and hurry up the apparatus I had sent for, and Mr. D. G. Wilson started out to hurry them up.

About this time A. McTuskey arrived, and requested to be allowed to go in. He having taken the course at Seattle, I consented, and he put on the "two-hour" apparatus and carrying also one of the "one-half hour" type which had now arrived, he started inside. About twenty minutes later McTuskey returned and informed me that the men were all down except the fire-boss. In reply to my question why he did not insist on the fire-boss taking the apparatus and bring him out, he informed me that none of the men could stand, much less walk. I suggested to Mr. Powell that a rope be sent for so that a man could go in and tie the men on and we could pull them out, and this was sent for. Realizing that through some cause the gas was being forced onto the men (these men had been inside for about eight hours) I then suggested that we extend a sort of life line of men and follow up as near as possible to try and grasp any chance of saving their lives. We started in, and Mr. T. Spruston, overman, Michel,

taking the lead, testing the air as he went, we succeeded in reaching the entombed miners. Only in the inside did Spruston detect any sign of CH_4, and then only a small cap. Having reached the entombed miners we started to haul them out (we had no stretchers). Spruston and myself pulled one man a considerable distance when Spruston got knocked out and left me. T. Mather, Michel, then gave me a pull with the same man and also left me, then, feeling pretty sick, I gave up and tried to make my way outside; but must have succumbed to the afterdamp. I was found afterwards and revived.

When this forlorn hope started in there were seven men inside including Alderson. I am glad to say that the conditions altered so that five of these men were rescued alive. What caused this sudden change in condition I am not certain. It may have been a cave. On the other hand, Mr. Wilson on going out to hurry up the supplies, found the trap-doors without any person in charge. One of these was propped open. Mr. Wilson requested the Inspector of Mines, Mr. Heatheote, to put some person in charge.

Reviewing the situation I might mention that the station at Hosmer has only been open since November 1st. There are practically no trained men as yet,* the intention of the British Columbia Government being that the inspectors would take the course in the Seattle Mine Rescue Station and that, with a suitable training station, corps of men could be trained. I had just returned from taking the course as I previously mentioned. A. McTuskey, previously mentioned, had taken about six lessons, while Spruston had taken two lessons. These two did not come up with the special train, but followed in another train. Alderson had been doing some training in Hosmer mines with the apparatus, therefore my preference for him. The incident of th first apparatus leaking I can only explain by the fa that when we arrived in the lamp-room at Bellevue was crowded with men, and the appearance of th Draeger apparatus created quite a sensation, it beir almost impossible to keep the men from inspecting ar generally handling the apparatus. The pulmot which I had left with the doctor was brought in, b was not tried on any of the twenty-one men, the re son being, so far as I can see, that the doctor did n realize the importance of the pulmotor. Afterwar Messrs. Wilson and Ashworth tried it on some me but informed me later that it would not work. O the Monday following I was able to satisfy Mr. As worth that the trouble was that they failed to mak an air-tight connection between the mouthpiece an the man's face. The pulmotor, I think, would hav given a good account of itself, had there been trained man there to handle it.

I might also mention that we have four "two-hour type apparatus at Hosmer. One of these had bee leaking, therefore I did not take it

I have not the least doubt but that if the chang had not occurred in the ventilation we could hav brought out the eight men successfully; and more, ha there been a trained corps of men on the spot with a reasonable time, I believe a great many of the twe ty-one men found dead at the leak on the high pressu line would have been saved, as these men all died CO poisoning, and practically all had time to put o their clothes and take their buckets with them whe they tried to get out.

It must be remembered that we were out of ou own district, as Bellevue is in Alberta, and we coul not assume the direction of affairs as we would hav liked, and as is necessary for the successful issue rescue work. As it was, we were only rendering vo unteer assistance. We have, however, this advantag that we learned some very valuable lessons. The are, not to depend on advice as to whether the appa atus is wanted or not, to treat every accident as th worst until we find different, and to make a mo thorough inspection of the apparatus before it is take into actual work. The necessity of having traine

*Editors Note.—This account was written early in February of this year.

n and attendants, with an appointed leader whose ers are to be obeyed, was proved. Sentiment uld have no place in the work, as this leads to the of life, probably endangering the life of the whole ty. Portable stretchers are absolutely necessary. portable station in a railroad car is also a neces-. The pulmotor ought to be in the charge of ned men, able to determine how far it can be taken de, so that the men have not to be carried long ances for treatment.

nother point,—on making my second trip out I felt hed and heavy. This I ascribed to putting the ap-atus on inside, as, although there may be sufficient to keep men alive, I question if there was sufficient d air for a person to take when putting on the eger apparatus. In other words, I objected to Alderson giving up his apparatus as I considered there might be some CO in it. My reason for doing the same thing after was that it looked selfish to keep Alderson inside taking all the risk.

Referring to the incident when Alderson returned inside, having dropped the spare apparatus and claiming that the potash cartridge was done, I think that the exertion of carrying the apparatus, probably in a great hurry, had exhausted his respiration bag and he had dropped the apparatus when he should have taken a rest.

I have tried to give you an account of our experience, and if there is any point that I have overlooked or is not clear, I shall be glad to explain the same.

The apparatus we have is the 1910 type.

CANADIAN MINING LAW

By J. M. Clark, LL.B., K.C., Toronto, Canada.*

rom the Transactions of the American Institute of ing Engineers.

(Wilkes-Barre Meeting, June, 1911.)

or some years past, those interested in the devel-ent of the increasingly important mining industry anada, have urged the adoption by the Dominion liament of a federal mining law, which would e the force and stability of statutory enactment. present, placer mining in the Yukon Territory is erned by the Yukon Placer Mining Act. All other ing under federal jurisdiction is governed by Or--in-Council and Ministerial Regulations.

the earlier stages of development, it is perhaps atter of neccssity that these important matters ld be so dealt with; but it is now felt that the has come when mining rights in the extensive ons under federal control should be put on a per-ent basis, and that any changes required from to time should be made only after full and open ussion in Parliament.

short sketch will suffice to indicate how vast and ed the interests affected really are.

hen the Dominion of Canada was instituted by Imperial Statute known as the British North rica Act of 1867 (which came into force by pro-ation on July 1 of that year), it comprised only present Provinces of Ontario, Quebec, Nova Scotia, New Brunswick; but provision was made for the sion of Newfoundland, Prince Edward Island, sh Columbia, Rupert's Land, and the North-West itories. Subsequently Rupert's Land and the h-West Territories were acquired, the Crown Col-s of British Columbia and Prince Edward Island admitted, and all the other British territories possessions in North America, with the islands ad-nt thereto, except Newfoundland and its depend-s, were annexed to Canada by Great Britain.

Canada, consequently, now comprises the whole of the northern half of North America, except Alaska, Newfoundland, and that portion of Labrador which constitutes a dependency of Newfoundland. All lands, mines, minerals, and royalties belonging at the time of the union to the several provinces of Canada (now Ontario and Quebec), Nova Scotia, and New Brunswick, are declared to belong to that one of the said several provinces of Ontario, Quebec, Nova Scotia, and New Brunswick, in which the same are situated or have their legal origin—subject, however, to any trusts existing in respect thereof, or any interest therein, other than that of the Province.

Each of the Provinces named has jurisdiction to make laws for the management and sale of its public lands, and of the timber wood thereon, and also as to property and civil rights in the Province.

With some exceptions, not necessary to be here specified, the same rules were made applicable to Prince Edward Island and British Columbia. But very different conditions and regulations obtain in the remaining parts of Canada.

Under the sanction of an Imperial Statute, the Dominion of Canada obtained a surrender of the lands and territories granted by Charles II. in 1670 to the Governor and Company of Adventurers Trading into Hudson Bay, known as the Hudson Bay Company; and Rupert's Land and the North-West Territory were consequently admitted into the Dominion as of July 15, 1870.

When the Provinces of Manitoba, Saskatchewan, and Alberta were formed, the lands, mines, and minerals, with slight exceptions, were not transferred to the Provinces, but remained the property of the Dominion of Canada, and subject to federal jurisdiction and control.

The proposed federal mining law must deal with the mines and minerals of these three Provinces, of all the Territories (including the Yukon Territory), and of certain areas of the older Provinces, principally the Indian lands and the railway belts of British Columbia. It must, therefore, deal with placer mining, coal, natural gas, oil, petroleum, gold, silver, copper, and the other minerals. The whole field must be covered and every problem of mining law solved.

*ecretary's Note—Mr. Clark, an eminent Canadian er, and joint author of the treatise on "The Law ines in Canada," has been requested by the Do-on Government to prepare a Federal mining law, presents this paper, by invitation of the Council, der to obtain, if possible, useful suggestions from bers of the Institute.—R.W.R.

The framing of this general law is regarded by mining men as supremely important, not only on account of the great interests actually and potentially involved, but also because it is looked upon as the first step towards the unification of the mining laws of Canada. The vital importance of such completeness, wisdom, and practical convenience being presented by the federal statute as will recommend it to the several Provinces for voluntary adoption is therefore self-evident.

While the Dominion has no jurisdiction over the mining laws of the Provinces which own mining lands, it is hoped that the provisions of the federal law, by reason of their excellence and efficiency, will gradually be adopted by the various Provinces.

To paraphrase a famous saying, this must take place, not by reason of imperial power, but by the imperial power of reason.

In this connection, a striking instance of concerted action by independent jurisdictions may be mentioned. Some years ago, an exceedingly well-drawn Act, dealing with bills of exchange and promissory notes, was passed by the Imperial Parliament. The same Act, with slight changes, was passed by the Canadian Parliament, and by a majority of the State legislatures of the United States; so that it may now be said that this statute governs the greater part of the English-speaking world!

There is no reason why the members of this Institute should not take a useful and active part in obtaining for the mining world advantages similar to those which have been thus secured by the mercantile communities of Great Britain, the United States, and Canada.

At the present time, a discussion of the fundamental principles upon which such a mining law as is proposed should be based, and of the merits and deficiencies of such codes as that of Mexico, would be interesting and instructive, as bringing together, in useful form, the results of close observation and varied experience of the mining laws of the world.

There is no danger that any form of the so-called "apex-law" will be again introduced into Canada. That law was once copied, under the influence of miners from the Pacific States, by British Columbia, but was finally abolished April 23, 1892, since which date the rights of the holder of a mineral claim are confined, in British Columbia, as in all other parts of Canada, to the ground bounded by vertical planes drawn through its surface boundary lines. The vested rights of claim owners who had located their claims under former acts were protected; and the "apex-law," in British Columbia, as elsewhere, has given rise to costly litigation, which seems inherent in the system of extra-lateral rights.

There are, however, other important questions to be discussed; such as how adequately to protect the prospector, without at the same time introducing the danger of "blanketing"; the function of discovery in the acquisition of mining title; the most useful forms of working conditions, and the most efficient methods of enforcing such regulations. Last, but not least, the ever-present and ever-troublesome questions of taxation and royalties must be considered.

Discussion.

Rossiter W. Raymond, New York, N.Y.:—It is satisfactory, but not surprising, to learn that there is no danger of the adoption in Canada of the apex-law w its extralateral right. I do not think that any co munity which has once experienced the evils of th system, and has escaped from them by abandoni it, would ever dream of returning to it. And Briti Columbia having had that experience, has doubtl furnished a sufficient object lesson for the wh Dominion.

Mr. Clark's hope that a federal law may be fram which will ultimately be adopted by the Provinc is not chimerical. Not only the commercial instar which he cites, but the history of our United Sta law, encourages such a hope. That law prescribes few conditions, leaving to local legislation freedom ordain others, not inconsistent therewith. For instan the form and the maximum dimensions of a mini claim and the minimum amount of annual "asse ment work," are prescribed, together with a f forms of procedure; but smaller dimensions, larg amounts of annual work by possessory owners, a additional forms of procedure, may be imposed local legislation or regulation. In many cases, es cially during the earlier period following the adopti of the Federal law (1870), this freedom was abu antly used, and locators of lodes or placers were oft obliged to do, for the maintenance of their possess titles, a good deal more than the United States st utes required; but gradually the convenience of u form conditions, working quietly, but continuous like the pressure of gravity, had its effect; and, at t present time, the local regulations of mining distri have been largely superseded by State or Territor statutes, which are, in the main, not only consiste but identical with those of the federal law. Anotl illustration is the manner of making and recordin mining location upon the public domain. It may se strange that the United States law prescribes nothi at all in this respect. It required the location to h certain essential features of shape, maximum dim sions, and relations to the discovery of a mineral posit within its boundaries; but it does not requ any particular form of record or proof of these f damental requirements. Indeed, the United Sta Government does not to-day possess either records maps showing what portions of its public mine lands have been appropriated by valid mining lo tions, and, being held under possessory title, do now belong to that domain. The explanation of t anomaly is historical. At the time when our gove ment had to do something in order to define its re tions with miners who were technical trespassers u the public lands, those lands constituted, in the ma a vast unsurveyed wilderness. A theoretically perf and properly guarded system for the record of min titles would have been impracticable of execution; Congress, therefore, did the best it could under circumstances. The punishment of trespassers be neither desirable nor practicable, it legalized the t pass, and left the parties concerned to settle their lations to one another according to the local r which they had themselves adopted in the several m ing districts, or which might be established for th by local legislatures, subject to a few more or l elastic requirements established by the United Sta as the real owner of the land. Meanwhile, the fa concerned were left to be proved by any kind of dence, documentary or oral.

In my judgment, this action of Congress, thou warranted under the circumstances so far as reco of location, etc., were concerned, might and could h been remedied, when these circumstances had gre

ed, by requiring records of location, etc., to be in or officially transmitted to the United States or general land office. But it is worthy of note without any such requirement, the effect of considerations of the certainty and safety of such ls has brought about a general uniformity of legislation, requiring them to be filed with the s of courts or counties, who will be responsible eir preservation from mutilation or destruction. not yet the duty of such officials to give notice e United States of such entries, affecting the f the United States to its public lands; but that nay easily be taken. Meanwhile, this narrative newhat chaotic progress may encourage the belief hat obviously wise and useful features of administration will, in the end, be adopted by communities pon which, when first promulgated, they are not y binding. In other words, it is worth while for eral government, like that of the United States e Dominion of Canada, to frame a system of mining law for its own lands, which will commend ceptance of its constituent States or Provinces n th administration of their own lands.

To his end, I think the first requisite is a survey of ands. Apart from the mischievous extra-lateral the greatest cause of confusion and waste in mining districts of this country which have been d by our mineral land law, has been the lack of ublic surveys as would permit the accurate definiof a mining location by reference to established arks. I do not know how far the Dominion has ded in the discharge of this public duty—one of ry first, in my opinion, which is incumbent upon vernment worthy of the name. At all events, that Mr. Clark's draft of a code will include on for immediate performance of this work. grants may have to be made in territory not rveyed; but this should be done under conditions which will secure their subsequent re-definition rence to the lines of such a survey, and will permit the readjustment of their boundaries so as to conform, if possible, to those lines. This will be comparatively easy, if the boundaries of the original location are required to follow the direction of the future surveys—e.g., to run N-S. and E-W. The purchaser or possessory tenant of a tract of mining land would never object to paying for a little more area here, or little less there, in order to conform to this obviously convenient rule — provided, of course, he were not haunted by the fear of losing problematical "apex-rights" by any variation in his lines. Under our present United States system, the locator determines, as well as he can, the course of the "apex," which he ondly hopes he has truly discovered, and is bound to claim a rectangle covering that course—under penalty of losing some or all rights, both extralateral and interalateral, if later developments should prove him mistaken. It might be a hardship to him to be required to draw his boundary lines in particular directions; although I am inclined to think that, in the long run and in the majority of cases, the result would be advantageous to our mining operators, by reason of their greater security of title. I have had to do with a large number of mining litigations, and I can recall few lode claims involved in such cases from which the lode did not depart, at some point, across side line; so that I am inclined to believe that, even under the "apex-law," the boundaries of locations might have been required (with some modification or conditions as to length and width), to run N-S. and E-W., with real advantage to locator. Be this as it may, I see nothing to prevent the adoption by the Dominion of Canada of a provision so well established and so universally approved in the sale of public agricultural lands.

Next in importance to public surveys is the official classification of the public lands to be leased, sold, or opened to prospectors. This classification should be, in my opinion, final and conclusive. If the land in question has been sold outright, say, at the price of agricultural land, and the grant or patent of the government, conveying the full common-law fee simple to its contents, usque ad astra, usque ad inferos, has been issued to the purchaser, then the original official classification of it, as agricultural, should not be disturbed by proceedings attacking the purchaser's title, on the ground that it was or is, in fact, more valuable for mining than for agricultural purposes. The government should occupy, in this respect, precisely the position of a private seller. (Of course, actual fraud, to which the purchaser was a party, might be pleaded against his title, but to no further extent and under no other conditions by the government than by any private party wronged by such fraud. That is to say, the government should itself bring suit for the abrogation of its grant or deed; and the latter should not be open to collateral attack in any private suit.) In short, the purchaser of anything from the government is entitled, in justice as well as policy, to know just what he gets, and to be assured that he really gets it. The danger that, through an incorrect official classification, mineral land may be sold at a lower price as agricultural land, is entirely insignificant compared with the importance of giving a clear and secure title to purchasers.

On the other hand, lands may be granted for agricultural purposes, with a reservation by the government of the mineral rights. In this case, a previous official classification is less important. Yet I think it might well be required to protect the government against unnecessary administrative complications. Any land which is officially classed as "mineral," had better not be sold as "agricultural"; and, in any case it is best that in such transactions, as in private bargains, both parties should clearly know what they are doing. In leases of mineral rights, it might be urged that the government should be able to increase its requirements upon proof of unexpected value of the property. One obvious answer is, that such a change should be practicable, if at all, only after a term of years. But a more conclusive answer is, that the mining industry should be taxed upon its annual product or profits; and such a tax will take care of all unexpected prosperity, without disturbing the conditions of mining title. I feel bound to say, however, that nearly 50 years of observation and experience have inclined me to believe that the acquisition by private parties or corporations of the full fee simple of public lands, including the mineral right, is better in the long run, than any system of leasing by the government. If such a system should be deemed advisable, then the condition of the retention of title should be, not a given amount of annual "work," but an annual payment of money. The requirements of "assessment work," under our United States law, is delusive and useless. The required annual payment of a sum of money would be much more effective in preventing the retention of possessory titles (which are

practieally, under our law, goverument leases) for speculative purposes.

The policy of requiring continued work as a condition of eontinued possessory tenure is not partieularly harmful with regard to metal mines, espeeially when, as with us, the amount of such work is trivial; but the governmental leasing of coal lands for limited periods, and upon eonditions of eontinual operation under penalty of forfeiture, is thoroughly bad. This idea has been suggested, I believe, by President Taft himself, whose sane and wise views of the general subject of conservation'' have won the approval of intelligent people. But I think he is wrong on this point. The operation of a colliery by a lessee is certain to eause the saerifiee of future to present interests; and the requirement that sueh a lessee shall keep going or lose his lease simply aggravates the situation. No governmental inspector could fairly require of a lessee the expenditure of a large sum of money whieh he might never reeover, under an arrangement subjeet at any time to executive eaneellation, espeeially if such expenditure were required, not for the safety of workmen, but only for the advantage of some future lessee; and the requirement of eontinuous operation as a eondition of tenancy, would operate to favour that over-produetion which is the greatest enemy of ''eonservation.'' At a recent meeting of the Institute, an eminent authority on this subject* read a paper advoeating the shutting down by the gov ment of coal mines that did not pay, in order to vent the injurious over-production and consequ waste of coal. My proposition is, that sueh mines be shut down by their proprietors without gov mental interferenee, provided they are not force eontinue operations for some other reason, such as danger of thereby losing their property altoget In short, I think that, in all sueh questions, pri ownership and liberty are likely to produce better sults than governmental supervision; and that best thing any government can do is to preserve der, enforce contracts, give to lessees or purchaser its lands clear and valid titles, and then allow t the largest praeticable liberty of enterprise and dustry—reaping its own advantages, not from the tortion of a pereentage of the anticipated result speculative adventures, but from the eonsequent creased wealth of all its people and the fair taxa of that wealth.

I could say many other things upon the text w Mr. Clark has presented, but I trust the foregoing incite other members of the Institute to offer sug tions whieh may be useful in his undertaking.

*Edward W. Parker, The Conservation of Coa the United States, Trans. xl., 601 (1910).

EQUIPMENT AT PORCUPINE

The following list of equipment already installed, or about to be installed, was furnished to the CANADIAN MINING JOURNAL by Mr. Alexander H. Smith, mining engineer, now resident in Porcupine. The list is not entirely eomplete, but it is nearly enough right to indicate the eondition of affairs early in April. Hardly any more additions will be made until after the railway is complete. Any omissions that may be noted have, of course, been made unintentionally.

List of power plants, etc., Poreupine Gold District, April, 1911—erected or under construction:

1. Armstrong-Booth—Boiler, hoist, and drills.

2. Armstrong-MeGibbon—3-drill Rand eompressor, boiler, hoist, and drills.

3. Bewick-Moreing No. 1—5-drill Rand eompressor, 6 drills, boilers, hoists. etc.

4. Bewick-Moreing No. 2—5-drill Rand compressor, 6 drills, boilers, hoists, ete.

5. Burns (Shaw)—10-stamp mill ordered with neeessary equipment.

6. Crown Chartered No. 1—3-drill Rand, boiler, hoist, drills, one MeKiernan-Terry shot drill.

7. Crown Chartered No. 2—Boiler and hoist.

8. Duncan Chisholm—One McK.-T. shot drill.

9. Dome—40-stamp mill, 1 Nissen stamp, eyanide plant, power plant, eompressor, ete.—largest plant in camp.

10. Dome Extension—3-drill Rand, boilers, hoist, drills, one McK.-T. shot drill.

11. ''Foster'' West Dome—Compressor, boi hoist, drills, and 4 MeK.-T. shot drills.

12. Foley-O'Brien—3-drill compressor, boilers McK.-T. shot drills, hoist, and drills.

13. Feldon—Reported 2 shot drills.

14. Hollinger—30-stamp mill, concentrating mi Tremaine steam stamp. boilers, compressor, h ete.

15. Imperial—Boiler and hoist.

16. MeEniney—Boiler, hoists, and drills.

17. Philadelphia—Boiler, hoists, and drill

18. Preston-East Dome—5-drill Sullivan compre boilers, hoists, drills, 2 Nissen stamps.

19. Pearl Lake—2 boilers, 2 hoists, 2 drills. McK.-T. shot drill.

20. Goldfields Consolidated (''Rea'')—5-drill pressor, boilers, hoists, drills, one McK.-T. shot d

21. Standard—Boiler, hoist, 1 drill.

22. Scottish-Ontario—Boiler and hoist.

23. James Whalen—Boiler and hoist.

24. Vipond—Compressor, boilers, hoist, and Nissen stamp.

In addition to the above, we have ascertained four additional McKiernan-Terry shot drills have installed on properties not mentioned in the list. T properties belong to Thor Warner, B. Babayan, balt Townsite Mining Company, and Catlin P Company.

ONE VIEW OF PORCUPINE

From our valued contemporary, the Mining Journal of London, we reprint the following remarks concerning Porcupine. The tone of the letter, which was written by the Journal's New York correspondent, is sound and the criticisms appear not unduly harsh.

THE PORCUPINE BOOM—For the past twelve months romantic stories of fabulously rich quartz veins have been issuing from the wilds of Northern Ontario, and, unless all signs fail, the campaign of educating the public through the press will be sufficiently advanced in the course of the next two or three months to permit of the launching of the Porcupine boom.

When the Cobalt field was first opened up, engineers for the most part reported adversely on the camp, and many of those who reaped the advantage of the richness of these unique deposits were people who had little or no previous experience in mining, and who, by the fortunate investment of a few hundred or a few thousand dollars, became rich within a short period of time. The great richness of the ore veins at Cobalt, and the proximity of the camp to the populous cities of the eastern part of the United States and Canada, caused the wildest sort of excitement, and set up a standard of prices never before witnessed, except in the early days of the Comstock lode

Following the discoveries of gold-bearing quartz in Porcupine less than two years ago. it was quite natural that the first people to interest themselves in the camp should be the mine operators of Cobalt, only a short distance away. These immediately applied the Cobalt scale of prices to undeveloped mining claims, thousands of dollars being asked for swamp land without even an indication of mineral. The readers of the Journal are already familiar with the geology and general character of the deposits at Porcupine.

The greatest secrecy has prevailed regarding the results of development work that has been carried on in the Timmins and Dome properties. The enormous quartz outcrop at the Dome property, with its spectacular showings of free gold, stimulated the imagination of many people, and the vague statements — and contradictory ones, too—that have from time to time been published, have only served to enhance the mystery surrounding this supposed to be fabulously rich property. A few people, perhaps, are in possession of the actual facts regarding the value of the ore proved by the development work in the Dome. The high standing of the group of financiers who control this property lends colour to all the stories published, despite the fact that the owners have never made a public statement about the values disclosed by the development.

The Hollinger mines. belonging to Timmins et al, share equally with the Dome in the romance of Porcupine.

The publicity agents of the district have assiduously informed the interested world every time an engineer of note has come into the district in the past six months. William Frecheville's name was published far and wide as indicating the interest London financiers were taking in the camp. When the Consolidated Gold Fields of South Africa entered the field there was a blare of trumpets, and daily the press is filled with announcements of transactions which are supposed to indicate the great richness of the field.

Aside from the recently published statement by M Timmins, as president of the Hollinger mines, the has been no definite statement made by anyone in a thority as to the assay value of any of the ore opene up. The general character of the statements regar ing the ore is that there are spectacular showings an rich development. As a matter of fact, the Porcupi deposits are by no means peculiar to that section the world, but have been exploited with indifferer success elsewhere, and absolutely reliable informatio based on results of sampling, indicate that most the engineers who have visited Porcupine have turne the camp down.

According to the statement of Mr. Timmins abo mentioned, on the Hollinger mine there have bee some 1,400 feet of development work. Based on th meagre amount of development, it is stated that t average assay value of the ore is $49 per ton. A cording to the "Boston News Bureau," the Hollinge has $3,000,000 in sight in a high grade vein of quar averaging 8 feet in width, which has been develope for 1,300 feet in length on the 100-foot level. A estimate of ore reserves on the Hollinger must taken with caution. There are only three shafts the property on the main ore zone, one of which h not been sunk to the 100-foot level. Before any a curate estimate of ore reserves can be made, a gre deal of additional work must be done.

Recently 100,000 shares of this company were o fered at $3.50 per share, and the price has since ris to about $8, giving a market value to the property $4,800,000. It is safe to say that the amount of d velopment work done does not warrant any such val ation of the property, and in view of the meag amount of information regarding the character the ore deposits at Porcupine, $8 for these shares unwarranted.

The people interested in the Dome property have record of success behind them in the mining worl which should go a long way in reassuring one th the property has merit. If the statements regardi the developments of the Dome property are to be b lieved, according to the "Boston News Bureau," a orebody 600 feet long by 350 feet wide, having a average assay value of $10 per ton, has been opene up at the 40-foot level. An orebody of these dime sions would contain 600,000 tons for every 40 fe vertical in depth. At the present time a 40-stamp m is being erected on the property, which may be e pected to crush about 75,000 tons per annum. In oth words, the 600,000 tons stated to exist above the 4 foot level will take about eight years to mine. Di mond drill holes are stated to have proved the co tinuation of values at considerable depth. An anal sis of this situation leads to the inevitable conclusi that an orebody of such dimensions and value wou be attacked in an entirely different manner, conside ing the experience and financial ability of the owne

We have yet to learn that a mine valuer of stan ing had made a report giving values which may used by the public as a gauge of the merit of the pr perties reported on. It is likely that the astute peop ple who are interested in the Dome and Timmins pr perties are fairly well convinced that they have pr perties of merit, and they most certainly expect make either out of the share market or the min

But this is a long way from proving that everyone of any of the other extremely numerous outcrops of the camp will prove of value; and a warning signal should be hoisted as a guide to the investing public that they must be careful lest they be bitten by the numerous flotations which are sure to come, and which will be placed before them in an attractive form inviting them to participate in the enormous wealth supposed to exist in Porcupine.

The history of gold mining in Eastern Canada has been one of uniform financial failure; and if for no other reason caution should be exercised regarding the Porcupine field until developments have reached such a stage as to indicate with absolute certainty the possibilities of the district, not only superficially but in depth. Lenticular bodies of quartz showing gold do not necessarily make paying mines

---

PRODUCTION OF LEAD IN 1910

(In tons of 2,000 lbs.)

By C. E. SIEBENTHAL.

Advance Statement of U. S. Geological Survey.

	1909	1910	P.c. increase
Production of primary refined lead	448,112	470,380	5.0
Primary lead available for consumption	370,013	376,021	1.6

SMELTER PRODUCTION.

The refined-lead product cannot be apportioned according to source of ore, owing to the fact that lead refiners treat smelted products whose origin may, as in custom refining, be unknown to them, the identity of the ore, and thus its original source, being preserved only as far as the smelter. Accordingly, the following table, showing source of lead smelted or refined in the United States, is based on smelter figures. It includes "pig lead" reported by all smelters using Mississippi Valley soft lead ores and "lead" produced at all other lead smelters in this country. The greater part of the product reported by smelters operated in conjunction with refineries is in terms of refined lead. A like part of the antimonial lead product is thus eliminated from the lead produced and appears only in the figures of production of antimonial lead. No lead ore from the United States was treated elsewhere during the period covered by the table.

Source of Primary Lead Smelted or Refined.

Grand total, derived from all sources	442,015	408,523	457,045	480,780

REFINED PRIMARY LEAD.

The following statement of the production of refined primary lead embraces all desilverized lead produced at works in this country, and the pig lead recovered from Mississippi Valley soft lead ores. The pig lead derived from Mississippi Valley ores and desilverized is shown separately. The antimonial lead reported by refineries is also given below. The original source of the ore and bullion affording this refined product is shown in detail in the accompanying table under "Source."

Production of Refined Primary Lead.

	1907	1908	1909	1910
Desilverized lead	284,432	265,564	296,891	301,223
Soft lead	99,948	101,013	118,801	139,318
Desilverized soft lead	29,809	29,856	32,420	29,839

Production of antimonial lead	9,910	13,629	12,896	14,069

PRODUCTION OF SECONDARY LEAD.

Pig lead	9,990	7,840	17,872	a27,354
Lead in alloys	15,508	10,443	33,040	a24,533
Total recovered lead ...	25,498	18,283	50,912	a51,887

CONSUMPTION.

In the following table "lead" includes all kinds—lead in ore, base bullion, pigs, bars, and old. The figures of domestic production are based upon returns by the smelters: all other figures are from the records of the Bureau of Statisties. Decrease by liquidation covers losses in smelting and refining in bond and other corrections. Warehouse stocks of bonded lead of foreign origin are given, but it has been found impossible to obtain at this time complete figures of domestic stocks. For this reason the result given below is "lead available for consumption." The "apparent consumption" of previous reports would be this quantity increased or diminished by the increase or decrease of domestic stocks during the year.

Consumption of Primary Lead.

Supply:	1907	1908	1909	1910
Stock in bonded warehouses, Jan. 1	5,756	12,944	18,565	17,405
Imports—				
For consumption	15,246	9,805	18,036	15,359

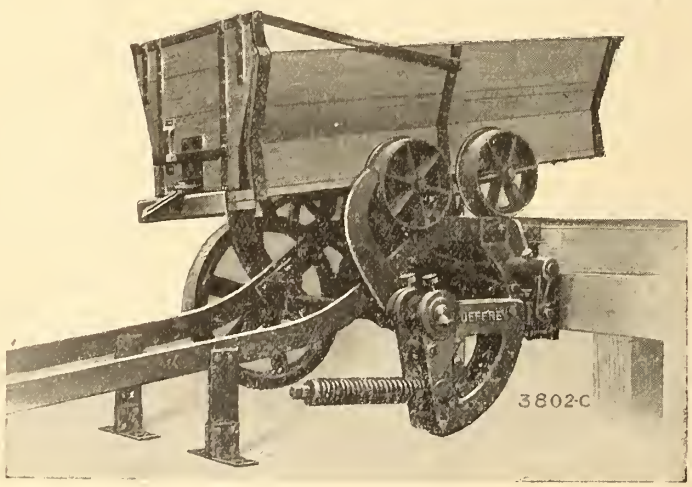
aSubject to revision.

JEFFREY-GRIFFITH DUMP

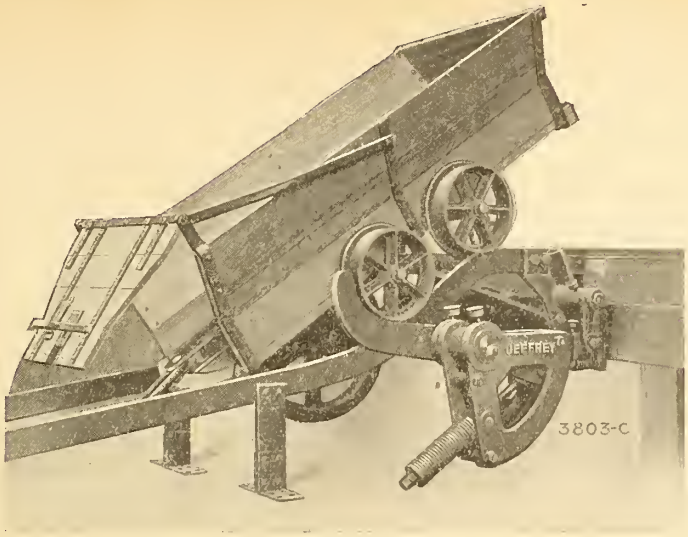
The Jeffrey-Griffith Patented Dump shown herewithillustrated in fig. 1, the jar being absorbed by th is one which has recently been developed As a cross-spring. over car dump, it possesses features which make the dumping or flow of the coal almost continuous in its Automatically the car assumes the dumping positio movement over the dump. No. 2, which is almost simultaneous with posi



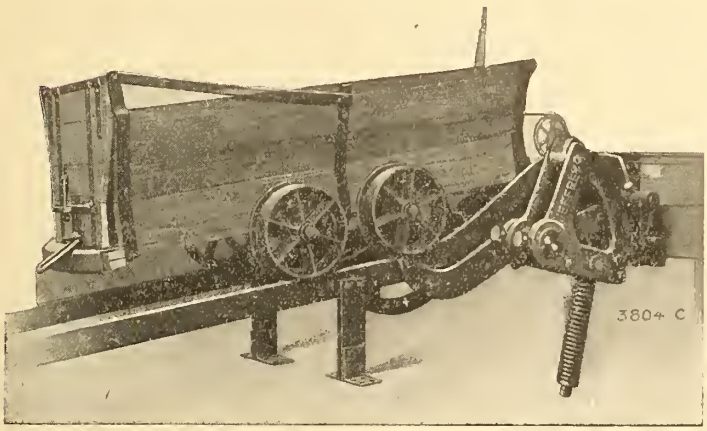
Entering.

This dump eonsists of two continuous rails to which are attached substantial horns, securely fastened to a heavy shaft; this shaft has a bell erank and quadrant with spring deviee seeurely attached to the one end, while at the other end is located a brake wheel and lever deviee for releasing the car after discharging its eoal. In operation, the cars pass over the knuckle as tion No. 1.

After the eoal is discharged, the ear is released b means of a lever (the only work of the operator) which allows it to pass over the track as in illustra tion No. 3 by depressing the horns whieh automaticall resume position for the next ear. This is done b means of the spring, whieh is of suffieient strength t



Dumping



Releasing.

the horns into the receiving position together with the rotating action of quadrant by gravity.

Te cars may be discharged over this dump per min- ute) that its capacity is only limited by the activity o" te man required in its operation. Its continuous rails make stoppage of operation due to derailment of cars n impossibility and also insure less breakage of coal nd less wear and tear on cars; its simplicity of desi n. operation and capacity, make it most desir- able or large as well as small mines. Its large dump- ing pacity is due to the quick and continuous action of the dump, shorter movement of the cars and the increased safety in bringing loaded cars close to the dumping position.

This is the only dump where the car maintains continuously its natural position throughout the operation. There is no break of hinge in the tracks to cause derailment of cars and blocking of the coal consequent thereto. As this dump occupies less space than other cross-dumps, the cost of the tipple building to house same is correspondingly reduced; less help is required because of simplicity and ease of control.

JAPANESE STEEL.

Th Government-supported steel industry of Japan, upon which $15,000,000 has already been expended, is calling for $6,000,000 additional to put it in a sound posi on. The works, situated at Wakamatsu, were take over by the Government in 1900. Large annual defic s have been recorded since then. In 1910 the de- fi it was $250,000. About 9,000 men are employed at the orks and collieries. Three blast-furnaces, each of 1 tons daily capacity; two 10-ton acid Bessemer conv rters, 11 basic Siemens-Martin furnaces, 25 tons each one crucible-steel plant; 13 rolling mills, etc., mak up the plant. The iron ore used is imported from Korea. It contains from 50 to 60 per cent. metal- he in n.

CARBORUNDUM.

Carborundum, the artificial abrasive, is manufactured by fusing a mixture of pure granulated coke, pure glass sand, and sawdust. Residnal coke from the distillation of petroleum is used. Sawdust is added to make the mixture porous and to prevent decrepitation due to the explosions of carbon monoxide produced during the reaction. The reaction between the sand and the coke produces carbide of silicon, or carborundum. The Carborundum Company, Niagara Falls, N.Y., uses 10,000 electric h.p. continuously. The carborundum crystals are crushed under manganese rollers and the crushed product is treated in a bath of sulphuric acid to dissolve the particles of steel that have been cut from the rolls. This treatment has been more effective than cleaning by magnetic separation.

SPECIAL CORRESPONDENCE

ONTARIO.

Porcupine.

Unless immediate steps are taken there will be a very serious epidemic of typhoid in Porcupine this summer. There is at present no water in any of the settlements except from wells, and, as analysis has shown, many of these have been contaminated. Golden City, the site that the Government sold, has good water in Bobbs Lake and arrangements should at once be made to pipe it over, the Government contributing. In the meantime, the sanitary inspectors are doing all they can to prevent the accumulation of refuse and are compelling the carting away and burning of all refuse, but without pure water these precautions are not likely to prove effective against an epidemic. Pipes are being laid from South Porcupine to Porcupine River for a temporary supply of water. With the promise that Porcupine now has of permanency, no time should be lost in obtaining water from the Matagami River. The Hollinger gold mine, a certain centre of mining activity, is within two miles, and there will be camps strewn all along the seven miles into South Porcupine.

West Dome Formerly Foster, Ferrodolomite

According to recent discoveries on the Hollinger, the other veins parallel to the one developed are likely to prove up well. Two crosscuts have been run from the 100-foot level of the main vein and in both places where a parallel vein has been cut the ore body has been found to be both large and quite as rich as on the developed lead. Good results are announced from the 200-foot level also.

Owing to the very late spring much machinery and supplies that would otherwise certainly not have reached Porcupine till after breakup have been taken over the winter road and will be installed and working before they c have been taken in under last year's conditions. There sh not be more than two months between the final breaku the winter trails and the running of the first train over T. & N. O. line.

The property of the Haileybury Silver Mining Compan the Township of Deloro has been sold to M. T. Rowland Arizona, for a company. Work will commence right away

It is stated that the option on the Ross veteran propert the east side of Porcupine Lake has been given up. A siderable amount of diamond drilling was done on this perty to test it up by an English company.

Work on the Imperial Gold Mining Company's propert Porcupine has been resumed after a month's cessation, w the plant was being installed. The main shaft has been 50 feet and the first work will be to crosscut to the vein. velopment work on the Apex Porcupine gold mines, near West Dome, has been commenced. Stripping will be conti and test pits sunk on the veins until machinery can be bro in.

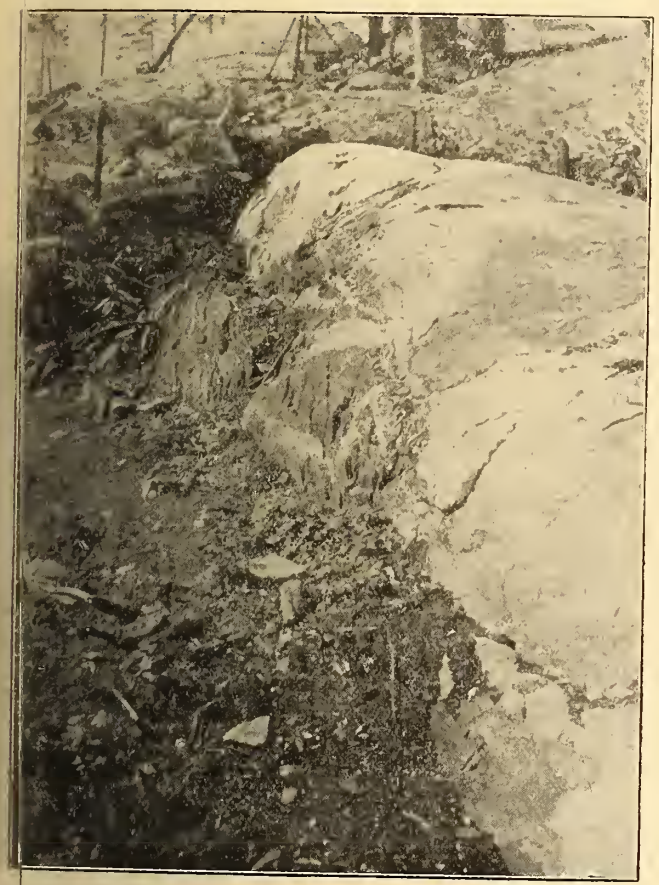
Several finds of free gold have been made recently in frey Township, near the west boundary. The latest what is known as the Futunda syndicate of Montreal, specks of gold have been found in the quartz at a dep six feet.

While there is not a single shaft sunk yet on any o hundreds of claims staked in the Keekeek country, 60 northeast of Haileybury, and little prospecting done, ther very considerable amount of interest. Several pioneer cluding Sam Le Roy, have good assays from wide vei

artz, and there is no question but that there will be much ivity between the Quinze and the Transcontinental during summer. The mining laws of Quebec have been so amended t it is much easier now for prospectors. The manager of the eat Lakes Dredging Company at Port Arthur is now work- the James claims with a good force of men. Last summer staker, Thomas James, opened up some very pretty free gold showings in a narrow vein.

Following a find of free gold to the west of Fort Matche- wn, on the Montreal River, a considerable amount of stak- has ensued. Isolated prospectors have been finding gold in this section for years, but it was not until Porcupine showed a endency to make good that much attention was paid to it.

With the Terry shot drill the veins on the Dobie and the Ea properties have been cut recently. The Rea ore taken fm 200 feet looks very promising, and the greater part of



Quartz Mass on the Dome.

th payments have now been made. On the Dobie, the drill na just entered the vein and the result is said to be satis- fa tory to the owners.

he West Dome, being developed under the direction of Mr. Wiss, has also found its vein at depth. The cores in this an ance are considered quite satisfactory.

Cobalt, Elk Lake, Gowganda, and Other Silver Fields.

he Nipissing is now operating a mill on its own property fo the reduction of its high grade ore. To date it has pro- du ed from the amalgamating and cyanide process specially ad pted to Cobalt ores by Mr. Chas. Butters and Professor Chenger, 307,690 ounces, and is getting an extraction of sc ething like 98 per cent. from 2,000-ounce ore and upwards. Experiment is now being made to see if the process cannot be ad pted to the treatment of low grade ores.

t Elk Lake, the Beacon Consolidated Mines is now install- in a plant. The company has the Cleaves claims and has a sh ft sunk 70 feet.

The March production of the Nipissing was of an estimated value of $185,332, while ore shipped amounted to $90,400. The Nipissing has produced to date $571,750, and has shipped $421,257 for the first quarter of 1911. This came from 1,260.50 tons, and ounces contained were 1,089,106.

The Crown Reserve has just declared the usual monthly dividend of 5 per cent., payable May 15. The statement shows an increase in the surplus, which now reads over $698,000. The Crown Reserve has now paid over $3,006,981, or 150 per cent., in dividends in May.

The Temiskaming Mining Company showed a surplus of $377,165 in its quarterly statement just before the 3 per cent. dividend was paid. This will amount to $70,000. Excellent ore is being raised at this date from the 575-foot level of the mine.

The Beaver has now entered the field of Cobalt dividend-payers, at the last meeting in Toronto declaring for a disbursement of 2½ per cent. on $2,000,000. The mill building project has been allowed to lapse until more ore has been blocked out.

At a meeting of the Temiskaming Mine Managers' Association, Mr. E. T. Corkill, Provincial Mines Inspector, was presented with a handsome chest of silver. Mr. Corkill has been identified with the camp ever since it was a camp, and has always been popular.

The Badger and the Bailey have entered the shipping list during the month. The Badger has not made a shipment previously; the Bailey not for some years in its own name.

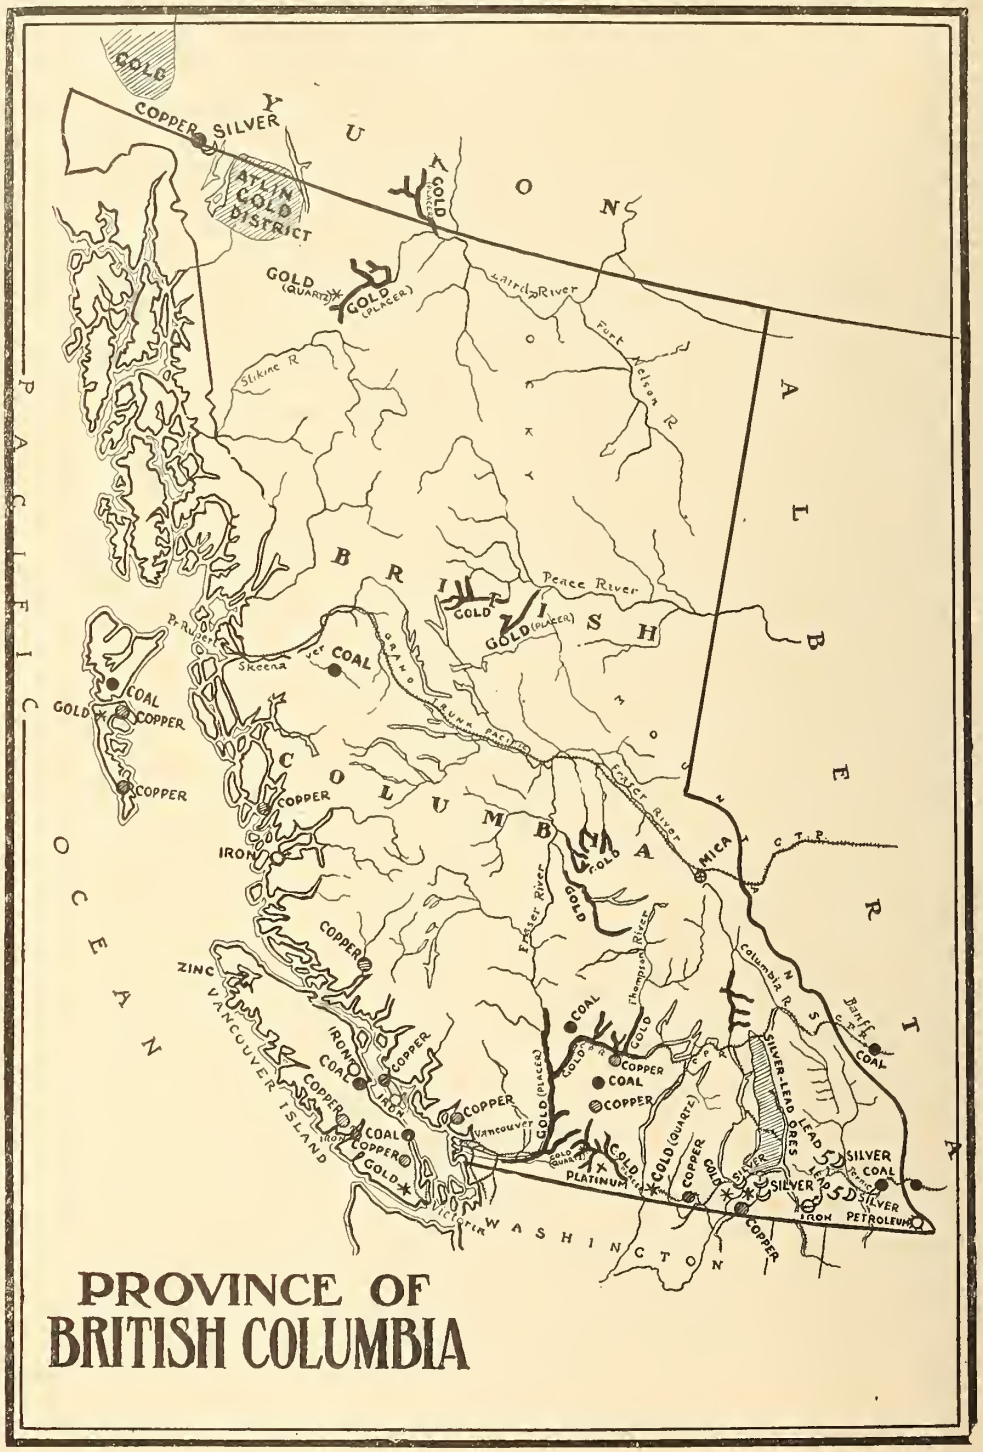
An overheated stove in the office of the Green Meehan mine set that building ablaze and it was burnt to the ground. It is isolated, and no damage was done to the rest of the property.

BRITISH COLUMBIA.

Reports from the placer gold mining districts of the province continue to show a general expectation of a larger recovery of gold this year than last, consequent upon there having been a heavier snowfall in the winter of 1910-1911 than in that of 1909-1910. In some of the placer mining districts much will depend upon the weather of late spring and early summer. If warm weather shall come early and cause a speedy melting of the snow, the gravel-washing season will not be nearly so long as under weather conditions favourable to a gradual exhaustion of the water supply extending well into the autumn. The hydraulic miners who operate on an extensive scale are prepared to move a considerably larger quantity of gravel than in recent years, besides which two or three hydraulic leases will be worked that have not been among those that have contributed to the production of the last few years if of any at all. There are several new mines in the Cariboo and East Kootenay, both of which districts may be expected to recover more placer gold during the ensuing season than for some time past.

The lode mining industry may also be expected to show a larger total of production this year, if there shall not be any serious interruption in mining and smelting as a result of labour difficulties in the Crow's Nest regions of southeastern British Columbia and southwestern Alberta. So far as lode gold, from stamp milling, is concerned, there should be a substantial increase in production, for the capacity of the Hedley Gold Mining Company's 40-stamp mill at Hedley, Similkameen, has been increased and auxiliary steam power, for use when the water power is not available, has been provided, so that it is likely the year's total tonnage of ore put through the mill will be larger by 5,000 to 10,000 tons, in which case the value of the production from this property will be greater by between 60,000 and $120,000. In Nelson mining division, too, an appreciably large increase may be looked for, both from mines within a few miles of the city of Nelson and those in Ymir and Sheep Creek camps. Much of the lode gold re-

covered each year in the provinces is from ores that are smelted, so the returns from these will materially affect the year's production of this metal. An early agreement between coal mine operators and their employees and a resumption of coal mining and coke-making without much delay will prevent a cessation of smelting at the copper reduction works. Most of the copper ores smelted in the province contain more or



less gold and silver in association with copper, so that the production of all three metals is smaller when the smelteries have to be closed for two or three months of the year. However, there is still room for hope that suspension of smelting operations will be avoided, so it is yet early to anticipate lessened production on this account. As a partial set-off to possible loss from the Kootenay and Boundary districts, there is reason to look for a larger production of copper ores in the Coast district this year than last, for the outlook for the Britannia mine, on Howe Sound, is reported to be brighter while an increased output from Texada gold-copper mines is expected, consequent on the Tyee Copper Company having leased the Van Anda group there and undertaken development work that will probably result in a return to old-time productiveness of the Cornell and Copper Queen mines, at Van Anda. Meanwhile the Marble Bay mine, in the same locality, continues to steadily produce a fair tonnage of ore of good grade, with promise of maintaining its output for a long while. Two or three mines higher up the British Columbia coast should be productive this year, and so add to the total tonnage of the Coast district as to make it higher than that for last year.

The quantity of ore mined in British Columbia for its silver

nt only is not considerable, that containing both lead ilver being far larger. Both these metals should be pro- in greater bulk this year from ores mined in Slocan t and, as compared with last year, from East Kootenay A small increase in silver and lead ores may be ex- l from Nelson mining division, and in less degree from nth belt of Rossland camp. Portland Canal will likely producing camp this year, and it is possible a little silver- ore may come from the Skeena district, occurrences there es containing silver and lead having been tested with raging results. Reverting to the Slocan district—the pects for at least half a dozen producing mines here are edly promising. The Rambler-Cariboo is prominent the mines of the district. The Kaslo "Kootenaian" published the following information: "Superintendent y, in his monthly report to the directors of the Rambler- bo Company, states that he has suspended shipment of til such time as the road shall again become passable for ons, and as a consequence he is devoting all his energy elopment work. In only one heading is he working in hat is the drift on the 1,050-foot level, where he still s handsome a face of ore as ever was seen in the mine. ore-bin and other convenient place of storage is now f ore. He is cross-cutting on the 900 foot level and ng on the 1,200-foot. The latter working has to be ex- l several hundred feet to reach the downward extension oreshoot already developed on the 700, 800, 900, and oot levels. As soon as he shall have sufficient power he egin work on the 1,450-foot level, which has to be pushed about the same distance as the 1,200-foot to reach the y. As the Rambler-Cariboo Company has received as- e that the Canadian Pacific Railway Company will build Three Forks a branch line to serve the Rambler-Cariboo ucky Jim mines as early as the weather will permit of y construction being undertaken, he is only awaiting the n survey of the line to begin work on a tramway from ver tunnel to the new site to which the concentrator will moved from its present location. The last smeltery re- received were those from two cars of Rambler-Cariboo ipped early in the month, which netted $2,087 and respectively."

ut Sandon and Cody there are Slocan mines that are ed to do better this year than last. While the Rich- Eureka group will probably maintain its excellent ore- g record, its near neighbour, the Slocan Star group, is tood to have mapped out for it a season's work that result in a larger output of ore than it has made for l years. The Ruth-Hope group, too, also near Sandon, arded as likely to do well this season. In the vicinity y, the Reco is reported to be again in ore containing a ilver value, the Noble Five group is stated to be in a n to resume production, and the Surprise may have its d new workings connected before the year shall close, ich event, with much improved ventilation to allow it done, stoping may be undertaken. The deep-level de- ent work done in the Surprise mine constitutes one of st important features of mining in the district during t two or three years. It has proved the occurrence of of ore down to a depth of 1,100 feet, and has also en- ed others to explore for ore at deeper levels than they reviously done. The Sunset is another Cody mine in development at depth has been in progress, and it is hoped that this will eventually result in a return of dividend paying days, so that mining in the Sunset may again be profitable.

From time to time information has been given concerning the several mines about Four-mile Creek, near Silverton, in which important developments have taken place and which have been proved to contain large bodies of ore. These are the Standard, Van Roi, and Hewitt-Lorna Doone groups. The showing of ore of shipping grade in the Standard has attracted much attention, for it is one of the largest ever opened in the Slocan. The Standard Silver Lead Mining Company, organized to acquire this property, has arranged to put in a 10-drill compressor plant, erect and equip a 100-ton concentrating mill, and construct an aerial tramway from the mine down to the mill site on Four-mile Creek, a distance of 8,400 feet. The compressor has been ordered from the Canadian Rand Company, together with a Pelton water-wheel, six Rand machine drills and accessories, and other plant. The Van Roi concentrator is reported to have been started in April; as much ore has been developed in the mine, the mill run should be continuous for quite a long time. The managing director of the Silverton Mines, Limited, owning the Hewitt-Lorna Doone group, is expected to arrive from England soon, and thereafter to decide whether or not to considerably increase the output of the Hewitt mine. The Enterprise and Eastmont, on Ten-mile Creek, have both been doing underground development, which is reported to have resulted encouragingly, so that these mines should be among the year's ore producers.

Ainsworth division has not made any considerable production of ore since, first, the closing of the Blue Bell mine early last year, and, next, the destruction by fire in the summer of 1910 of the Whitewater concentrator. Work has been continued on the Whitewater group, including the Deep. The Utica, situated between Whitewater and the south fork of Kaslo River, is stated to have an excellent showing of ore, to deal with which the erection of a concentrator is projected. Several mines in the vicinity of the town of Ainsworth are looking well and promise a larger production of ore this year. In the Lardeau, the recent finding of more ore has been reported from the Silver Cup, near Ferguson, and the outlook for the Beatrice, a silver-gold-lead property situated on the Fish River of one slope of the Lardeau mountain ranges, is regarded as good.

Coal mining is active in the Coast, Nicola, and Similkameen districts. At the time of writing little coal is being produced in the Crow's Nest district, for only one colliery has its men at work mining coal, namely that of the Corbin Coal & Coke Company, which has an agreement with the United Mine Workers of America covering a period to expire on May 8. If by that time no arrangement shall have been made for the operation of the other collieries of the district, the Corbin mine will have to stop producing, pending the completion of negotiations for a general resumption of work at all the collieries. Much might be written concerning the expansion of the coal mining industry of British Columbia, and the consequent increase in production of coal, but just now space restrictions prevent this being done. For the present, then, all that will be stated is that the industry certainly is being developed to an extent indicating a much larger annual production of coal as the years shall pass.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax—Prospecting for gold and tungsten is more active this spring than for some years. At Waverley, 13 miles from this city, the scheelite property that belongs to Mr. H. C. Borden and his associates, is showing up in a most promising manner.

fax county at least three gold mines have changed hands.

Port Hood—The collieries of the Port Hood Richmond Railway Coal Company are being again worked up to capacity. During the winter nothing but development work was done, and the mines were put in much better shape than before. The two steamers belonging to the company have been placed in commission and a very active summer is looked forward to.

ONTARIO.

Cobalt—The power siege in Cobalt is over. All the big mines taking air from the Cobalt Hydraulic Company are working full capacity again. The other company—the British Canadian Power Company, expects to start compressors next week.

Toronto, Ont., April 14—One of the officials of the T. & N. O Railway states that they have every expectation of handling freight and passengers to Porcupine before July 1. But they could hardly see their way to giving in the meantime partial service by rail to Frederickhouse River and thence by launch on the river. By the 18th they will have the steel to the river, ten miles from the main line. There will be 10 miles of navigation from where the steel crosses the Frederickhouse on the way to the gold camp.

Porcupine, Ont., April 18.—In the crosscut from the main vein at the 100-foot level of Hollinger another vein now shows in the face. It is 6-foot wide of quartz. This crosscut is near No. 1 shaft, and about 100 feet away from the other crosscut tapping the same vein.

ALBERTA.

Frank, Alta., April 14.—At the meeting of the Executive Board of District 18, United Mine Workers of America, held here yesterday, that body decided to comply with the request of the Minister of Labour that they apply for a board of conciliation, and after sending a short wire to the department stating that they had decided to do so, they followed it up with an application at length, which was filed late this afternoon, and a copy given J. D. McNiven, Fair Wage Officer.

The official telegram is as follows:

"Hon. W. L. MacKenzie King, Minister of Labour, Ottawa —Without prejudice to our case in any way, and acting in accordance with your apparent desire to have the machinery set in motion at the earliest possible moment, to establish a board under the Industrial Disputes Investigation Act of 1907 to investigate matters in connection with the failure to renew the agreement between the Western Coal Operators' Association and District 18, United Mine Workers of America, we hereby make application for such board to be established. While believing that at all times we have acted strictly in accordance with the laws of the Dominion, we realize that it is the desire of the Government to have this matter thoroughly investigated and we are desirous of extending co-operation to this end, as we firmly believe that there can be no permanent peace in the mining industry of this country until the wage questions are settled on a basis of equality."

The parties to the dispute are the Western Coal Operators' Association, composed of the following companies: The Crow's Nest Pass Coal Company, Hosmer Mines, Limited; Corbin Coal & Coke Company; International Coal & Coke Company; Western Canadian Collieries; Canadian Consolidated; Hillcrest Collieries, Limited; Leitch Collieries, Limited; Alberta Railway & Irrigation, Limited; H. W. McNeill & Company, Limited; Bankhead Mines, Limited; and District 18 of the United Mine Workers of America, representing the organized employees of the aforementioned companies to the number of about 6,000, who ceased work at the expiration of the agreement of March 21, 1911.

"The United Mine Workers of America are contending for substantial increase in wages and the elimination of irregularities that exist in contract rates, day wages, scale, hours of labour, and general conditions. The attempts to arrive at settlement are embodied in the minutes of the joint conference that was held in Calgary during March last and which will be attached to the formal application. If it will be acceptable to the department, we will set forth our claims in full, together with formal applications as soon as it is possible to do this, and forward copies to the other party as well as to the department. The name of the person suggested by ourselves as representative is Mr. A. J. Carter, of Fernie, B.C.

"(Signed)—W. B. Powell, President; C. Stubbs, Vice-President; A. J. Carter, Secretary; J. E. Smith, J. D. Jones, McNabb, W. Lees, members of the Executive Board of District 18, U.M.W. of A."

All the members of the Executive Board were present, and the decision was unanimous. Mr. McNiven has with him the necessary forms for filling in names and dates, so that the mine workers, having named Mr. Carter as their representative on the Board, it remains for the operators to act quickly in making their choice so that no more time is lost in getting the Board to work.

Satisfaction is expressed in all quarters at the action of the mine workers to-day.

Vice-President Stubbs stated that in taking this step they were actuated merely by a desire to have the disputed questions between the operators and miners permanently settled. Had the operators in making their offer of arbitration, acted upon an open fair basis at Calgary, the miners would gladly have accepted. That not having been the case, they had relied on the Minister of Labour in his request for an application for a Conciliation Board, which gave both sides an equal chance in the choosing of a board.

BRITISH COLUMBIA.

Phoenix, April 14.—Although the strike in the Crow's Nest Pass coal mines, if prolonged, may cause a cessation of operations with the Granby Company, such an occurrence is not looked for, according to F. M. Sylvester, assistant to General Manager Jay P. Graves.

The Granby Company has sufficient coke on hand to keep the entire battery of furnaces at the smelter in operation for about six weeks, or by running five furnaces, operations could be continued till the middle of June.

The coke consumed represents about half the smelting of Granby ore, so that the freight charges on coke from more distant collieries prohibits the consideration of such a move at the present price of copper.

Asked concerning the Hidden Creek mine, Mr. Sylvester stated the development work continues with gratifying results and it is altogether probable that the Granby will exercise its option which expires in the course of a few months.

The Granby is also looking for the development of a valuable producer in the claims recently bonded on Copper Mountain, at Chesaw, which are now being explored with the diamond drill. The ore is largely copper and iron, and the property will be convenient to the company's smelter.

At the Cliff mine, Rossland, the Granby has a force of 35 men at work, and it is expected regular shipments will be commenced during the summer.

Nelson, B.C., April 17.—It is reported that J. T. Hillis and Dr. A. R. Baker have purchased a controlling interest in the famous Nugget mine, in Sheep Creek, and that new management will install a cyanide plant and stamp mill.

COMPANY NOTES

Abstract of General Manager's Report, Nipissing Mines Co.

April 1, 1911.

David Fasken, President, Nipissing Mining Co., Ltd.,
Toronto, Ont.

Dear Sir,—I beg to submit report of operations for the year ending December 31, 1910.

Shipments in 1910.

	Dry Tons	Gross Ounces Silver	Net Value
High Grade Ore	1531.792	3,999,580.48	$2,018,152.21
Low Grade Silicious Ore	4834.3315	1,008,357.79	427,069.68
Concentrates	319.12	296,490.55	145,805.27
Nuggets	13.6865	293,349.79	151,294.07
Total	6698.93	5,597,778.61	$2,742,321.23

Average Assay of Shipments.

	Oz. Silver Per Ton.	Cobalt.	Nickel.
High Grade Ore	2611.04	9.35 p.c.	6.72 p.c.
Low Grade Silicious Ore	208.58		
Concentrates	929.08	6.46 p.c.	2.68 p.c.
Nuggets	21433.51		
Average of total	835.62		

Summary of Shipments, 1910.

Dry tons shipped	6698.93
Gross Ounces Silver Contained	5,597,778.61
Gross Silver Value	$2,991,891.09
Average Price received per oz. cents.	53.447
Cobalt paid for—pounds	167,532.
Received from sales of Cobalt	$ 16,109.89
Gross Silver Value plus Cobalt paid for	3,008,000.98
Smelter Deduction, Treatment and Freight	265,679.75
Net Value received from Ore Sales	$2,742,321.23

Cost of Producing Silver.

Based on production of 6717.26 tons containing 5,548,651.91 oz.

		Per Ton Shipping Ore.	Per Oz. Silver
Mine Operation—			
Trenching	$ 23,385.75		
Development and Exploration	185,370.32		
Shaping	85,388.41		
Ore Sorting and Loading	27,944.13		
Jigging	1,340.76		
Sampling Shipments	15,641.83		
Assaying and Engineering	8,777.06

1910	13,397,860	5,597,778.61	2,742,321.23
	43,120,979	18,345,238.78	$9,438,908.30

Dividends Paid.

	By Nipissing Mining Co. Ltd.	By Nipissing Mines Co.
1905 To Syndicate	$ 300,000	
1906 To Syndicate	100,000	
To Nipissing Mines Co.	500,000	$ 480,000
1907 To Nipissing Mines Co.	880,000	840,000
1908 To Nipissing Mines Co	740,000	720,000
1909 To Nipissing Mines Co.	1,370,000	1,350,000
1910 To Nipissing Mines Co.	2,122,500	2,100,000
	$6,012,500	$5,490,000

Development.

The usual amount of development and exploration was done through eight shafts and two tunnels. Two new shafts, No. 127 and No. 141, were sunk to explore veins in the Keewatin.

The former is in the northeast corner of the main property near the O'Brien; the latter is near the Gillies Limit in the extreme southwestern corner. The developments have not been very favourable in either.

The work was distributed as follows:—

Drifting	feet	4,480
Crosscutting	feet	1,913
Raising	feet	1,054
Sinking	feet	567
Total	feet	8,014
Stoping	cubic yards	9,810

Surface Prospecting.

The trenching gang worked six and a half months during the season of 1910. An average of 61 men dug 31.7 miles of trenches to an average depth of 2.7 feet. The work was confined largely to the central area which had already been prospected.

Three veins were found in the conglomerate and eleven veins in the Keewatin. No. 134 to No. 147 inclusive.)

The most important of these is vein No. 141, which is now being developed by a shaft; other veins that were worked are No. 143 and No. 145.

In addition to trenching, some prospecting was done by an hydraulic jet.

A small centrifugal pump already on the property was put in operation as an experiment and the bedrock was washed clean over an area of several acres.

The results showed that it would be feasible to operate such a plant on a large scale, so that during the coming season a turbine pump capable of delivering 4,800 gallons of water per minute, under a head of 415 feet, will be installed. It will be run by a 700 h.p. motor.

Present Surface Condition.

	Total Acres.	Partly Prospected.	Unprospected.
Conglomerate	429	306	123
Keewatin	176	166	10
Diabase	241	16	225
Total	846	488	358

Concentration.

The custom plant of the Nipissing Reduction Company, Limited, has continued to treat the low grade ores of vein 63 with the following results covering the period from December 31, 1909, to December 31, 1910:

Dry weight concentrates tons	13,537.4805
Silver contents ore ounces	400,479.63
Average assay ore ounces per ton	29.58
Weight concentrates produced dry tons	326.431
Silver contents concentrates ounces	314,105.80
Average assay concentrates ounces per ton	962.
Net value of concentrates	$153,893.55
Profit of Nipissing Mining Company	$108,020.60

Jigging Plant.

A change has been made in the marketing of the low grade silicious ores, a large tonnage of which has heretofore been sent to the smelters.

The run-of-mine is hand-sorted on picking tables fitted with a one-inch or larger screen; the undersize, which was formerly shipped, goes to a small jigging plant where it is classified and jigged, the tailing going to the custom concentrator. The slime and very fine sand are shipped to the smelters, as it was found uneconomical to concentrate them, but this product constitutes only about 10 per cent. of the whole.

Reduction of High Grade Ores.

A small plant has recently been erected at the mine, to test on a working scale, a process originated by Mr. Charles Butters for the treatment of high grade Cobalt ores.

It has been the earnest desire of the company to find a method by which the silver in the first class ore could be extracted economically and shipped as bullion without going to the considerable expense of erecting the usual smelting plant. To this end, a great many processes have been investigated and some have been tried on a small scale

The results so far in the new plant have been most encouraging; bullion is now being shipped and it is confidently believed that the undertaking will be a success.

Ore Reserves.

The following estimates of developed and partly developed ore include high grade ore only; the large tonnage of mill rock on the dumps and in the mines is not covered by the estimates:

	Oz. Silver.	Gross value at 50c. per oz.
Vein 63	762,250	$ 381,125
" 64	924,080	462,040
" 73	2,127,850	1,063,925
" 80	1,384,100	692,050
" 86	40,000	20,000
" 100	723.600	361,800
" 122	591,000	295,500
	6,552.880	$3,276,440

Results of the Year.

The results for the past year have been most gratifyin both production and profits have exceeded those for any sir lar previous period. Notwithstanding a production of ov five and a half million ounces of silver, enough additional was developed during the year to fully replace the lar output.

The cost of producing silver was reduced from 16.39 ce to 14.71 cents per ounce.

Silver was sold for an average of 53.447 cents per oun compared with 51.547 cents in 1909.

The net profit after deducting expenses of every kind $2,167,103.50; this is 72.6 per cent. of the gross value of ore produced.

Very truly yours,
R. B. WATSON,
General Manag

In its annual report shortly to be issued, the Nipiss Mining Company will announce that a process has been fected whereby all high-grade ore from Nipissing and La R will be reduced to bullion in a plant which has been erec and has already produced 300,000 ounces in silver bars year. The process will be modified to treat low grade ore.

ONTARIO GOLD FIELDS DEVELOPMENT COMPANY

It has been announced by cable that the Northern Ont Exploration Company has incorporated a new developm company for the purpose of dealing with its interests in Porcupine district. The new company is registered under name of the Ontario Gold Fields Development Company, wit capital of $3,000,000, in 600,000 shares of $5 each. The i provides for a working capital of approximately $450,000 addition to the plant and machinery laid down during the two months by the Northern Ontario Company, estimated $50,000. This will give them, at the disposal of the comp half a million dollars.

The directors are: Cyrill Wanklyn, chairman; W. B. Law Johnstone, Hon. Frederick Carson, Charles Algernon More David Richards, managing director of the Northern Ont Exploration Company; D. A. Dunlap, of Toronto; and Cha Hart, of Montreal. The latter two represent the Timm McMartin group.

The Canadian public will have the advantage of a dent committee in Canada comprised of Noah A. Timm president of the Hollinger Gold Mines; Hy. L. Timmins, John McMartin. Messrs. Bewick, Moreing & Company become the general managers. The bankers in London wi Messrs. Robert Lubbock & Company, and in Canada, the adian Bank of Commerce. The secretary and officers wi located at 20 Copthal Avenue, London.

Mr. Lovell, who will be the technical manager, reside Canada, will arrive in the course of the week.

REA CONSOLIDATED.

At a meeting of the Rea Consolidated Gold Mines, ited, the following board of directors was elected: Charl Hill, president Hillcrest Collieries, president; Directors

Butler, vice-president and general manager Canada Car & adry Company; D. Richards, of London, Eng., Canadian esentative of Bewick, Moreing & Company; Thomas H. of Chicago; Henry Lockhart, Jr., New York, manager es Finance Company; John B. Holden, barrister, is acting etary as well as director; L. C. Thompson, Montreal. The tal is $1,000,000, in 200,000 shares of $5 par value. 20,000 es are held in the treasury, and $100,000 in cash. The com- has 321 acres in Tisdale. Up to April 6th, $70,000 has expended in working and equipping the property. The d of directors have entered into a contract with Bewick- eing & Company, to act as managers of this property. e blocks of stock are owned by a Montreal syndicate, Mines Finance Company, and the Consolidated Gold Fields outh Africa.

CONIAGAS DIVIDEND.

niagas directors have declared a quarterly dividend of 6 per cent., and an additional bonus of 3 per cent., payable on the 1st day of May, 1911. This is the same as the last previous payment in January.

DOBIE MINING COMPANY.

The Board of the Dobie Mining Company is as follows: Frank C. Armstrong, president; E. P. Earle, vice-president; D. Lorne McGibbon, Hon. Wallace Nesbitt, and Samuel Dobie, directors. The authorized capital is 300,000 shares of $5 par value; 60,000 shares are held in the treasury. The Dobie Mining Company will start operations with $100,000 cash and 60,000 shares of stock in the treasury. Of the 240,000 shares, 220,000 shares were given to the owners in payment of the property; 20,000 shares were purchased at $5 a share by the Tisdale Mining Company to provide $100,000 for development purposes; 60,000 shares of stock remain in the treasury. Underwriting of 120,000 shares is offered at $4 a share.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

here were new shippers on the Cobalt list for the week ng April 14th, namely, the Badger, of South Coleman; an Bailey Cobalt, of Giroux Lake. Shipments for week and ye in pounds of ore follow:

	Ore in lbs. April 14.	Ore in lbs. Since Jan. 1.
Badger	55,200	55,200
Bailey	40,000	40,000
Beaver	.....	595,243
Buffalo	.....	746,990
Chambers-Ferland	64,000	384,900
City of Cobalt	66,000	362,280
Cobalt Lake	.....	1,315,000
Cobalt Townsite	.....	280,740
Colonial	42,000	42,000
Coniagas	126,800	1,355,890
Crown Reserve	66,000	659,520
Hargraves	.....	41,100
Hudson Bay	.....	185,930
La Rose	87,000	1,359,700
Kerr Lake	120,200	961,808
King Edward	.....	40,000
McKinley-Darragh-Savage	51,600	1,711,660
Nipissing	79,700	1,900,460
O'Brien	.....	401,710
Peterson Lake (Little Nip)	.....	58,430
Right of Way	.....	318,260
Silver Cliff	.....	183,180
Standard Cobalt	.....	44,813
Temiskaming	.....	503,612
Trethewey	.....	326,030
Wettlaufer	.....	60,022

llion shipments during week:

	Ounces.	Value.
Nipissing, 72 bars	72,243	$36,850
Buffalo, 15 bars	12,800	7,000
Kerr Lake, 2 bars	2,000	1,008

OUTPUT OF ROSSLAND ORE.

The Consolidated Mining & Smelting Company of Canada, Limited, ore receipts at Trail smelter for week ending April 15th and year to date, in tons:

	Week.	Year.
Company's mines—		
Centre Star	4.398	55,100
Snowshoe	1,849	25,355
Sullivan	578	10,106
Richmond-Eureka	50	760
St. Eugene	132	2,070
Other mines	943	22,303
Total	7,950	115,694

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending April 21, and those from Jan. 1, 1911, to date:

	April 21 Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	56,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	.....	595,243
Buffalo	58,400	868,010
Chambers-Ferland	.....	384,900
City of Cobalt	.....	362,280
Cobalt Lake	123,200	1,438,800
Cobalt Townsite	62,100	351,840
Colonial	.....	42,000
Coniagas	63,170	1,410,060
Crown Reserve	118,600	778,130
Hargraves	.....	41,100
Hudson Bay	.....	185,950
La Rose	311,930	1,671,630
Kerr Lake	120,000	1,081,898
King Edward	.....	40,000
McKinley-Darragh	118,890	1,823,450
Nipissing	146,130	2,046,590
O'Brien	.....	401,710
Peterson Lake (Little Nip)	.....	58,430
Right-of-Way	.....	318,260
Silver Cliff	.....	106,680
Standard Cobalt	.....	44,813
Temiskaming	65,090	568,702
Trethewey	.....	326,030
Wettlaufer	.....	117,232

The shipments for the week were 1.087,510 pounds, or 543 tons.

The shipments from Jan. 1 to April 21 were 15,066,028 pounds, or 7,533 tons.

Prompt and Satisfactory Returns

The North American Life is continually receiving from policyholders unsolicited letters like the following, expressive of their appreciation of the treatment accorded them and results attained:

The holder of Policy No 8192 wrote:—
"I appreciate the promptness with which you have remitted the amount due me. I may say that I have nothing but praise for your company for the very satisfactory way in which I have always been treated. Our business relations have been very pleasant and I wish the North American Life the future success it so well merits."

The holder of Policy No. 9205 said:—
"I cannot close matters with the company without expressing my great appreciation of its methods and the very fine manner in which I have been treated by its representatives. In the 20 years of dealing I can recall no single instance in which I have received anything but courtesy and business promptness. I hope to renew relations with the North American soon in respect to my children's insurance."

The Financial Position of the Company is Unexcelled.

Nissen Stamp Mill

The Nissen Stamp Mill

STAMP. The Nissen Stamp drops with great crushing effect upon a feed comparatively free of the fines caused by preceding impacts. This causes an actual splash which radiates from the centre of the die, carrying the pulp to a circular screen, every aperture in which presents a full opening for the pulp which has already reached size to pass through. As the stamp ascends preparatory for the succeeding blow, a partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated type "B" Nissen Mortar.

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Address P.O. Box 331
Toronto, Canada.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definately the precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.

NEW BRUNSWICK and NOVA SCOTIA

1107. Joint Report on the Bituminous or Oil Shales of New Brunswick and Nova Scotia. Also on the Oil Shale Industry of Scotland. Part I, Economics, Part II, Geology by R. W. Ells.

QUEBEC

1077. Memoir No. 7, Geology of St. Bruno Mountain, Quebec, with maps, by J. A. Dresser.

ONTARIO

1059. A Geological Reconnaissance of the region traversed by the National Transcontinental railway between Lake Nipigon and Clay Lake, Ontario. Accompanied by two maps covering the region, by W. H. Collins.
1082. Memoir No. 6. Geology of the Haliburton and Bancroft Areas, Ontario, by Frank D. Adams and Alfred E. Barlow.
1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.

NORTH WEST PROVINCES

1035. Coal Fields of Manitoba, Saskatchewan, Alberta and Eastern British Columbia accompanied by a map, by D. B. Dowling
1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1093. Memoir No. 2. Geology and Ore Deposits of Hedley Mining District with maps, by Charles Camsell.
1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1101. Memoir No. 5, Lewes and Nordenskiold Rivers Coal District, Yukon Territory, by D. D. Cairnes.
1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1906 by A. W. G. Wilson.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postage.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

ORE TESTING

is the vital part of Mining, No matter whether you are a prospector in the field or the president of a mining company—you have ores to test. And upon the knowledge of your ores depends your success—your fortune. With a

Way's Pocket Smelter

you can become personally acquainted with your ores. Making tests by **Way's Process** is full of absorbing interest. You can test for one or more metals in a single operation, at the cost of a cheap cigar. If $5 of your money goes for assays, in a year, write us before you spend another cent.

WAY'S POCKET SMELTER CO.

P.O. BOX 819

South Pasadena, California

Wri Your Name On The Margin

of this and with your address and we will send you a copy of our new 5031 work booklet—valuable in itself.

A MESSAGE
TO
MINE SUPERINTENDENTS
WHO HAVE
IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners, Chilled Wheels and Castings of all descriptions.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unsurveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minimum being 40 acres in unsurveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries.
Quebec.

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTI

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native orm; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. It **does not freeze,** or rather, explodes with perfect efficiency when frozen and **needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appear ance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines

Nobel Monobel, Saxonite and Carbonite.

ECONOMY OF STEAM
IN
THE POWER HOUSE

The Condenser is as old as the steam engine itself, but has until very recently received far less consideration and has been treated as an anxiliary, the reliable working and effieiency of which had but little bearing upon the economy of the plant as a whole.

With the advent of the steam turbine and the demand for higher economies, the importance of the condensing apparatus has become more clearly apparant, and it now holds its rightful place as one of the principal parts of the steam plant.

Our independent air pump and jet cone condensing apparatus will save from 20 to 30 per cent. in steam when applied to non-condensing steam engines, or will give an increase of power of corresponding amount. It can be attached readily and placed in the most convenient place.

We get the best results by designing and building condensing apparatus specially to suit the conditions of operation.

THE CORE TELLS

The accompanying photograph shows four sections of a diamond drill core recently secured in drilling for limestone near Auburn, California, by the Mountain Quarries Co. The average length of the cores is nine feet four inches, and their diameter, $\frac{15}{16}$ of an inch. They were removed with a Sullivan "Class H" Diamond Drill, using a ten foot core barrel. The cores, it will be noted, form a perfect record of the rock formation from which they were cut.—"MINE & QUARRY."

THE Core tells where your ore or coal is, what it is worth and how best to reach it. It tells these things with an accuracy that cannot be doubted, and more quickly and cheaply than you can obtain this knowledge in any other way.

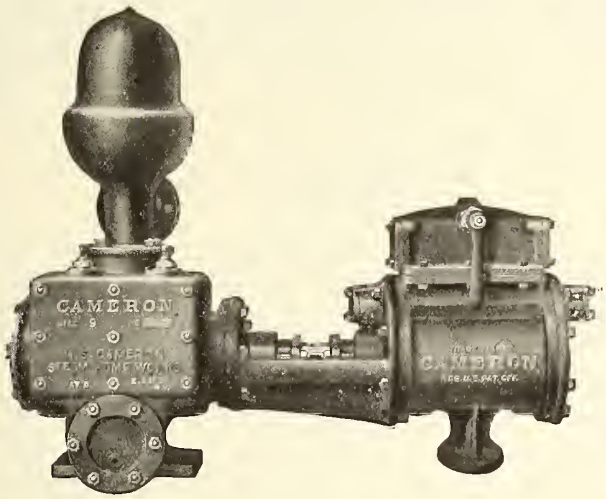
Cameron Slogan
"CHARACTER: THE GRANDEST THING."

CAMERON MINE PUMPS



The superior construction of the "Cameron" pump is, we believe, a pretty well known and generally acknowledged fact, however, lest it be forgotten, we desire to draw your attention to some of the contributing factors of this characteristic.

The "Cameron" has fewer working parts than any other steam pump made. The steam mechanism consists of four strong, simple, durable parts, all working in direct line with the piston, with no valve rods, tappet bars, rollers or clamps to become bent, broken or get out of alignment.

The Cameron valve mechanism, entirely inside the cylinder is positive and reliable. There is no dead centre and the piston cannot reverse until it has completed its full honest stroke and delivered the full volume of fluid.

A notable mark of convenience in the Cameron is that the inlet connection may be made on either side of the water cylinder and the discharge flange may be turned at any angle desired.

The above are only a few brief facts which are substantiated by details in our pamphlet "K 112," which we will be glad to send on request.

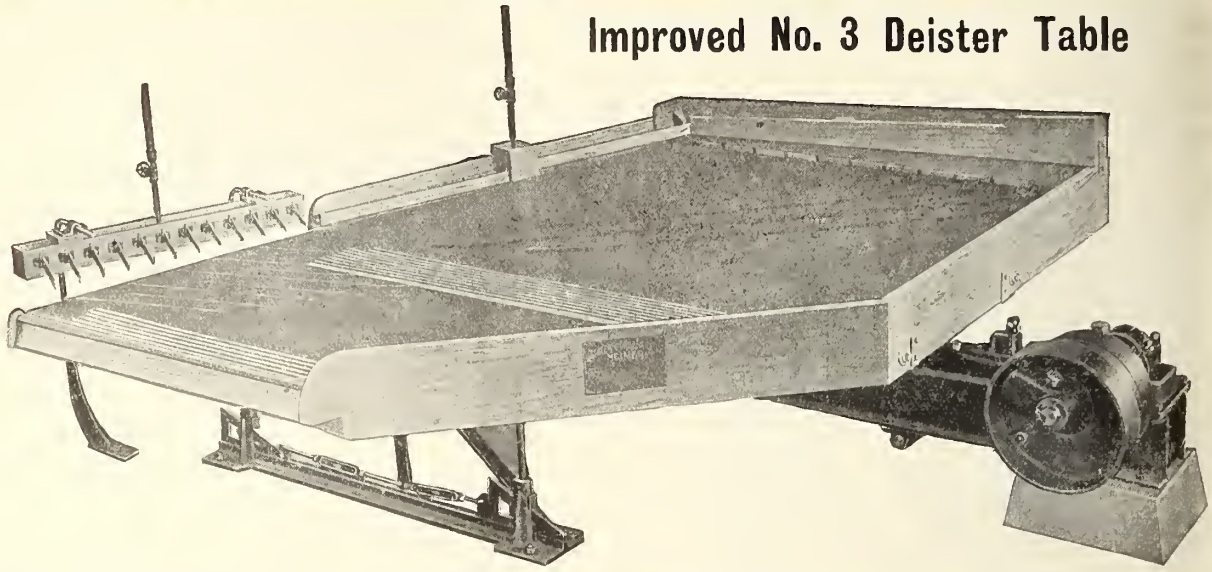
Improved No. 3 Deister Table



THE vanner has been a most efficient type of concentrating device for a decade. Competitive tests in such well known mills as **Goldfield Cons. Mines Co., Goldfield, Nevada; Miami Copper Co., Miami, Arizona; Stratton's Independence, Ltd., Victor, Colorada; Old Dominion Copper Co. Globe, Arizona** and **Detroit Copper Co., Morenci, Arizona,** have proven the Improved No. 3 Deister Table superior in efficiency on feeds of 80 mesh and finer. A pleased customer remarks: "Your No. 3 Table does as good work for us as vanners at a tithe of the cost for repairs."

Amatite ROOFING

Why the Buyer of Amatite Never Complains

When a man buys ordinary ready roofing he neglects to paint it and after three or four years he comes back to the dealer with a protest. It is human nature to neglect painting roofs.

When a man buys Amatite Roofing be lays it on his building and in three or four years it is still as good as new and does not need any paint. He forgets he has such a roof but no harm is done by that.

There is nothing to neglect in the case of Amatite. Amatite has a peculiar surface—a sort of plastic concrete made of pitch and mineral matter.

This surface is plastic enough so that the material can be rolled up into handy rolls in the usual manner and handled just like any other ready roofing. When unrolled on the roof and nailed down it presents to the weather a continuous surface of mineral matter and pitch. On this surface wind, rain, storm, heat and cold have little effect. Year after year it looks up to the sky undisturbed and unaffected. It costs nothing to maintain and relieves the owner from all responsibility.

Dealers can improve their business by selling Amatite and buyers make a good bargain when they buy it. The price of Amatite is less than that of most painted roofings of less weight and durability.

Samples free on request.

Address our nearest office.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

MILLING AND MINING MACHINERY

Shafting, Pulleys, Gearing, Hangers, Boilers, Engines, and Steam Pumps, Chilled Car Wheels and Car Castings, Brass and Iron Castings of every description, Light and Heavy Forgings.

Alex. Fleck Ltd. - Ottawa

Genuine Satisfaction

If you have anything to do with Rock Drills, you have, probably, been disgusted with them many times and wished you were running by hand. You are striving for fewer delays, lower mining costs, increased tonnage, and increased profits, and cannot afford to leave anything untried which would aid in the attainment of the above.

Can you afford therefore to pass by

THE

"Cleveland" Stope Drill

and not give it a trial when we can guarantee that it will relieve you of this part of your troubles.

There are so many reasons "why" that we haven't space enough here to enumerate them, but will you please

ZINC.

We note that the London price of spelter has risen steadily until latest quotations are £24 2s. 6d. per ton. This is very gratifying to the zinc ore producers and is due to several causes, chief among which are the daily increasing uses of zinc and its products, and the gradual decrease in the supply of spelter on hand in the United States for export.

The zinc industry in the Missouri field has taken a new lease of life and the producers are looking forward to a revival of the prosperity and general good times of 1905 and 1906 and the early part of 1907. During that period the miners received from $50 to $58 per ton for 60 per cent. zinc concentrates, and the lead market reached a maximum of $88 per ton. This latter price, of course, was somewhat inflated owing to certain peculiar phases of the metal market, but nevertheless the ore producers profited by these conditions.

Ontario and British Columbia have several zinc prospects which could be converted into shipping mines if smelting conditions were altered. At present British Columbia is exporting a raw material of high grade, and the country as a whole is gradually increasing the volume of its refined zinc imports. The British Columbia ores could be largely supplemented by the product of Ontario mines if smelting conditions were favourable. We already have the ore. We should be getting our share of the benefits due to gradually increasing interest in this important industry. Let the Government act.

PUBLIC INFORMATION.

Repeatedly have we called attention to the fact that amongst certain mine owners there is a decided disinclination to make public the facts concerning the physical condition of their properties. Generalities cannot take the place of specific data; nor can glittering hopes do duty for actual statements of fact.

In our last issue we had occasion to reprint from a contemporary a very sane article touching on the Porcupine boom. For this we were called to task by a local paper. Certain figures were quoted to show that one mine, the Hollinger, is in an extremely favourable position. Had this answer come from the manager of the mine, we would have accepted it without qualification. Unfortunately no official statement has been issued by Mr. Robbins. This is unwise and regrettable. Mr. Robbins' reports when he was manager of the McKinley-Darragh mine at Cobalt, were models

of accuracy and completeness. A report of this kind can hardly be expected from the Hollinger. But a definite official statement of some kind is absolutely necessary. Even if the public had no right—and a right they certainly have—to demand this, it is desirable to correct all the vain things that are being said and published.

What is true of Hollinger is equally true of all the other flotations. It is cheap and nasty to depend upon the subsidized enthusiasm of the baser sort of newspaper correspondent. Nothing but good will result from full and frank publication of facts. The responsible mine manager is the only man who can provide these facts adequately and rightly.

MARITIME OILFIELDS, LIMITED.

The foresight and perseverance of the organizers of Maritime Oilfields, Limited, will bring their deserved reward if appearances are not entirely deceptive. At the company's New Brunswick gas and oil property a total measured flow of 37,500,000 cubic feet of gas per day has been developed. Considerable oil has also come in, and there is definite promise of large quantities in the future.

Of the thirteen productive wells all yield oil. Initial flows of oil as high as 60 barrels per day mark the maximum. But the backbone of the enterprise is the company's arrangement to supply the city of Moncton, a centre that has large industrial possibilities, with a cheap, plentiful, and highly efficient fuel.

Moncton's present demand is estimated at about one billion cubic feet per annum. Undoubtedly this will increase. New factories and new homes will be multiplied. Not only Moncton, but the whole surrounding country will be directly and indirectly enriched by the exploitation of this new source of fuel.

We note with approval the fact that the New Brunswick fields are being developed in such a manner as to prevent unnecessary waste and loss. Only one well per thirty or forty acres is being sunk. When the time comes to treat the area as an oil-field, it will be easily possible to sink additional wells for every five acres.

We reprint elsewhere an account of the annual meeting of Maritime Oilfields, Limited. A perusal of that report gives the impression that Dr. Henderson and his associates are to be warmly congratulated.

GOLD MINING IN WESTERN ONTARIO.

Under the above heading Mr. W. E. H. Carter writes in this issue of mining districts that from 12 to 15 years ago made as much stir as Porcupine. As Provincial Inspector of Mines, Mr. Carter had special facilities for observing and recording. The general tone of Mr. Carter's article is not discouraging. It is clearly stated that certain factors that contributed towards the lack of success were well within human control. Moreover, the reader is given food for thou in other directions. With much cheaper transpo tion, with better professional talent available, with a public that has a keener and more direct i est in mining than ever before, it may be quite sible that not a few of the gold mines of Western tario will amply repay investigation. A boom is necessary. But we suggest that it would be good ness for investors to look into the merits of a dis that, so far as we can judge, has never had fair

EDITORIAL NOTES.

At the annual provincial exhibition, British umbia, the mineral and mining exhibits will includ types of modern mining and milling machinery. T exhibits will be amongst the chief features.

Advertisements of Porcupine stocks in certai our contemporaries are curiously similar in tone matter. Comparisons with the Rand, usually to detriment of that region, are common. More mon is the exploitation of the merits of the engi in charge of the property. The long-suffering John Hays Hammond is constantly suffering eclip

The gross receipts of the Witwatersrand Deep during 1910 were £709,833. The net profits amou to £290,049, and dividends to £271,824. The yiel ton of ore was 29s. 10d. The total cost of mi treatment, etc., was 16s. 2d., and the profit per was 13s. 8d. Ore reserves to the extent of 1,69 tons are proved. The average value per ton shillings.

The serious phase assumed by the revolutio Mexico has alarmed foreign investors. No longer the trouble be regarded as an inconsiderable i rrection. It is, in scope and effect, a revolution. I dent Diaz apparently must drop out of office—a t cal enough ending to a life that has been crowded gratified ambitions.

The company that publishes Everybody's Mag also publishes a monthly that is devoted largely t past doings and undoings of George Graham Rice. reports have it that Rice is to promote a Porc scheme. It will be instructive to watch the u which he will put his publishers.

The muck-raking habit has caught hold of American magazine. Particularly refreshing is Cosmopolitan June issue. In the text is a seve dictment of graft and corruption. In the advert pages is the advertisement of a thorough-paced cat. The advertisement states that Canada co not one metal refinery. Other glaring untruth obviously visible. Cosmopolitan should be thoro ashamed of itself.

CORRESPONDENCE.

DIAMONDS IN BRITISH COLUMBIA.

Editor Canadian Mining Journal:—

Sir,—Concerning the recently reported finding of diamonds in British Columbia, it should be noted that Mr. Robert A. A. Johnston, curator of the Geological Survey museum, who discovered small diamonds in some rock from Olivine Mountain, Tulameen district, British Columbia, has lately been quoted in a press despatch from Ottawa as having said: "The discovery is of no commercial importance. I have found it impossible to separate the diamonds from chromite and other varieties of rock in which they appear in the specimens found, without necessarily breaking them into small pieces. Of course, we could do this with a slow process, but commercially this would be out of the question."

Another press despatch quotes Mr. Chas. Camsell, also of the Geological Survey, as having suggested that diamonds may be found in the wash in streams near Olivine Mountain. I have no means of ascertaining—without delay—whether or not Mr. Camsell did so express himself, but I may say that if he did, his suggestion may, I think, be accepted as based upon reasonable conclusions. Mr. Camsell has during the four years last past done valuable work in investigating the geology and economic mineralogy of the Similkameen district of British Columbia, and two seasons of this time were spent in the Tulameen, which is in the northern part of the Similkameen district.

My object in writing on this subject is to make it quite clear that diamonds of commercial value may yet be found in the Tulameen region of this province, the small specimens discovered by Mr. Johnston, assuming him to have been correctly quoted, are so small and occur under such conditions as to make them valueless from the point of view of the prospector and miner.

British Columbia had last year's experience with gross misrepresentations relative to gold in the Portland Canal district; now it is risking similarly damaging notoricty in respect to Steamboat Mountain; and even the Tulameen district is being shown under false colours. This last statement is made by me after reading in two of the leading daily newspapers of this province a notice of the alleged doings of the Platinum-Gold Fields Company, Limited, which, it is asserted, has proved 6,000 feet of Tulameen River with a Keystone drill, in which 6,000 feet "the actual value in gold and platinum is estimated at $1,160,000. . . . The scene of present operations is just above the Nickel Plate mines at Hedley, which last year yielded a net profit of $200,000." Since there is absolutely not the smallest connection between alluvial gravels of Tulameen River and the Nickel Plate lode mines situated in mountains downstream and 40 miles away, the deceptive intent of the reference to the Nickel Plate seems obvious, though only to those who know the situation. It will be well that the actual position in regard to the finding of diamonds in this province be made perfectly plain, so that no disappointment and loss may occur by reason of lack of knowledge of the facts.

E. Jacobs.

Victoria, B.C., April 17, 1911.

Obituary.

Mr. James C. Fuller, who since the Le Roi mine at Rossland, B.C., has been operating on only a small scale has been performing the duties of surveyor and assayer as well as mining engineer, met his death as a result of having apparently drunk a solution of potassium cyanide in mistake for water. At the time of the sad occurrence he was alone in the mine laboratory. The mine foreman, answering a telephone call while engaged in his own office, heard Mr. Fuller say "Oh, Pete," but no more, so he hastened to ascertain the reason. The assay office was not far away, and about 75 yards from it he found Mr. Fuller lying at the foot of some steps. He was still breathing but died in a few minutes, before the arrival of a doctor, who had been hastily summoned by telephone. He had on one hand an asbestos mitt, and in the other a sandwich, while near where he fell the small tongs, with which he handled the cupels when assaying, were found. On the table in the assay office were several beakers, containing fluids, and one had been capsized. The fluid spilled was pronounced by other chemists as potassium cyanide. The conclusion was that while attending to his assay work, Mr. Fuller was also eating his lunch and made a mistake in drinking from the cyanide beaker instead of the one containing water. A coroner's jury, after enquiring into the circumstances, returned a verdict of accidental death. Mr. Fuller received his first mining education at the Camborne School of Mines, Cornwall, leaving there to go to Rossland, whence he accompanied Mr. A. J. McMillan from London in 1904. Ever since, with the exception of short periods spent in Rhodesia and Mexico, respectively, on mining engineering business, he had been employed in various capacities at the Le Roi mine. For several years he was chief engineer, under Mr. A. G. Larson, superintendent. He was held in high regard by all with whom he came in contact, and the management bears willing testimony to his ability as an engineer. He was to have been married in June, proximo. The body was interred at Vancouver, B.C.

Capt. B. A. Wroughton, commander of B division of the Northwest Mounted Police, Dawson, Yukon Territory, when in Vancouver, B.C., last month, was reported to have told a newspaper representative, among other things, that "There was very little mining on the creeks during the winter by private individuals, as the rich ground has been pretty thoroughly worked out. Properties have now mostly passed into the control of large corporations which successfully adopt modern hydraulicking and dredging methods during the summer months. The outlook is bright, and the output this season promises to surpass the figures of recent years. There are enormous areas of ground available, and, in fact, the supply of gold is almost inexhaustible. At least twenty dredges will be in commission this season, the majority operated by the Yukon Gold Company, controlled by the Guggenheims. The Boyle outfit last fall completed a gold dredge which has the distinction of being the largest in existence. It will operate this year for the first time on Bear Creek, where the pay dirt is rich."

Personal and General

Mr. J. Edgar McAllister has retired from the position of general manager of the British Columbia Copper Company, Limited, at Greenwood, B.C., and is now the company's consulting engineer, with headquarters in New York. Mr. E. G. Warren, assistant general manager, is now in charge of the company's affairs at Greenwood.

Mr. D. C. Botting, state coal mine inspector, Seattle, Washington, and Mr. J. B. Warriner, mine inspector for the Northwestern Improvement Company, of Tacoma, Washington, owning several important coal mines in that state, were recent visitors to Nanaimo, where they were shown local mines. They were accompanied by Mr. F. H. Shepherd, chief inspector of mines for British Columbia.

Mr. W. H. Trewartha-James, general manager of the Tyee Copper Company, Limited, has returned to Victoria, B.C., from a business visit to England.

Mr. Anthony J. McMillan, liquidator of the Le Roi Mining Company, is again in Rossland, after an absence of several months in the East and England.

Among other mining men who visited the coast cities of British Columbia last month were Mr. James Cronin, of Spokane, formerly manager of the St. Eugene mine, East Kootenay, and Mr. H. L. Rodgers, manager of the Yankee Girl mine, Ymir, B.C.

Mr. Robert R. Hedley, now consulting engineer for a British Columbia mining development company, with headquarters at Vancouver, B.C., has been nominated as chairman of the Western Branch of the Canadian Mining Institute, in succession to Mr. Wm. Fleet Robertson, provincial mineralogist, whose year's term of office will expire this month.

Mr. Robert Musgrave (B.Sc. McGill, 1903) has returned to British Columbia from Mexico. After graduating Mr. Musgrave went to the Copper Queen mine, Arizona. Later he was general superintendent of the El Tigre mine, Ysabel, Mexico. Latterly he has been representing a British company in Mexico.

Mr. Oscar V. White, superintendent of the Byron N. White Company's Slocan Star group of mines, near Sandon, has returned to the Slocan to resume mining on that important silver-lead property. He was accompanied by Mr. B. N. White, president of the company.

Mr. Robert H. Stewart, general manager of the Consolidated Mining & Smelting Company of Canada, Limited, is back at Trail, B.C., from a visit to Los Angeles, California.

Mr. John B. Hobson, of Victoria, B.C., took a trip to California early in April. He intends, shortly after his return to British Columbia, to proceed to Quesnel Forks to commence the season's hydraulicking on his placer gold mine on Spanish Creek, Quesnel mining division.

Mr. Wakely A. Williams, superintendent of the Granby Consolidated M. S. and P. Company's big smelting works at Grand Forks, B.C., recently visited Chesaw, northern Washington, where the company has commenced the exploitation of a group of mineral claims it holds under bond and option of purchase.

Mr. R. P. Williams, of Vancouver, B.C., has resigned the position of western representative of the Canadian Rand and Jenckes Machine Companies, after having been 21 years with the former company. His first visit to British Columbia was made in 1892, in connection with putting in a plant at a slate quarry on Jervis Inlet. He was in this province again in 1893. In 1897 he was in charge of the Rand and Jenckes machi sales office at Rossland; afterwards he removed Greenwood, in the Boundary district, where he mained for three years, but returned to Rosslan 1902. Last year he transferred his headquarter Vancouver. The territory he covered in the capa of representative of the two companies included tish Columbia, Alberta, and Yukon Territory, w for the Ingersoll-Rand Company he sought busine Alaska. His plans for the future are not yet defin decided.

A newspaper despatch from Seattle, Washing states that Thos. Hodgens, of Butte, Montana, and York, on April 28th filed suit against M. K. Rod a mining engineer well known in the West, asking a judgment of $203,000 against Mr. Rodgers, an order restraining him from foreclosing a mort against the Hidden Creek group of mineral claim Observatory Inlet, B.C. The complaint alleges Mr. Hodgens supplied $417,000 to Mr. Rodger purchase and develop mining properties in Br Columbia, and that the latter has declined to acc for any money except that used in purchasing an veloping the Hidden Creek property.

On April 13 the steamer Northwestern arrive Seattle, Puget Sound, Washington, from Cord Alaska, with the first cargo of copper ore from th terior of the mainland of Alaska. The shipment sisted of 1,100 tons of ore from the Guggenheims' anza mine at Kennicott, Chitina region. The n paper account of the enthusiasm aroused by the rival of the steamer at Seattle indicates that much portance is attached to this commencement of pro tion of copper by interior mines of Alaska. The o of unusually high copper tenor, and contains as silver to the stated value of $25 per ton; it wil smelted at Tacoma, at the head of Puget Sound. Copper River and Northwestern Railway, only cently completed, is nearly 200 miles in length, Cordova to Kennicott. It was constructed by the genheim-Morgan interests at a cost of about $20, 000.

A Board of Conciliation and Investigation unde Industrial Disputes Investigation Act, 1907, has appointed to investigate the labour troubles in lberta and Southeastern British Columbia coal mi districts. The Western Coal Operators' Associa nominated Mr. Colin McLeod, of Macleod, Alberta its representative, and the officers of District 18, U Mine Workers of America chose their secretary, M J. Carter. These gentlemen were not able to a upon a chairman, so the Minister of Labour appoi Rev. C. W. Gordon (Ralph Connor), of Winnipeg. board afterwards met in Lethbridge, Alberta, bu fore entering upon its work of investigation, ef were made to get the two parties concerned to to an agreement without the lengthy enquiry would otherwise be necessary. The Operators' A ciation first held a meeting at Macleod, and afterw met the representatives of the U.M.W. of A. in L bridge, but the adjustment of matters concer which the Operators' Association and the repres tives of their employees are not in agreement was brought about, consequently the Board of Conciliation and Investigation proceeded to make arrangement holding its meetings and conducting its investigat

REPORTING ON PROSPECTS

Written for the Canadian Mining Journal by W. E. Segsworth.*

In writing this article I merely desire to set down a few ideas that have crystallized during the course of me, in the hope that they may be useful to others. I wish to disarm criticism by saying that many things which I have said might have been said better by others, or may be disagreed with. I may also have left unsaid many things that may seem to be of more importance to others than what has been said here. If, however, the article results in helpful discussion it will have served one of its purposes.

The examination of a prospect calls for cool judgment, close observation, wide experience, and the ability to weigh against each other many conflicting considerations. In addition to this the engineer must have the power of detaching himself from his own personal prejudices.

Undoubtedly the main facts to be ascertained are:

First, Is any ore exposed on any of the boundaries of the property?

Second, What is the average value and width of the ore exposed?

Third, Can the determined grade and width of ore be worked at a profit under the surrounding conditions?

Fourth, What are the prospects for the continuance of the ore, or for its increase or decrease in value?

To obtain answers to these questions, it is advisable to keep in mind the lines of inquiry that may be followed with profit. It will, of course, be understood that in any one prospect probably not one-half of these lines of inquiry are of immediate importance. Those that are of no importance can be quickly eliminated and attention concentrated upon those remaining. I give below a list of the important points.

Prospects of Ore (Economic Geology):

(a) Is there any ore exposed on any of the bounding planes of the property? If so, what is its length, breadth, and value?

(b) Is the formation favourable to the kind of deposit examined?

(c) Is the formation in which the deposit occurs likely to continue in depth; or to change? If so, what effect will it have on the deposit?

(d) Is the formation much faulted? If so, what effect will it have on the prospects of holding the ore, or the cost of working?

(e) What type of deposit is the one examined? What conclusions may be drawn as to its probable size, continuity, and value?

(f) Are there any evidences of secondary enrichment?

(g) Does the deposit show the effect of surface weathering? If so, to what depth?

(h) Effect of eruptives?

(i) Blind veins?

(j) Evidence to be gathered from surrounding properties?

Metallurgy:

(k) Can ore of the probable extent and value indicated by the exposures be treated at a profit under existing conditions?

(l) If the ore is to be smelted can a suitable smelting mixture be made with the materials to be had within an economically possible freight rate?

(m) What influence will the process of treatment have on costs?

Costs of Operation:

(n) Transportation.
(o) Labour.
(p) Supplies.
(q) Development, cost per ton.
(r) Stoping, cost per ton.
(s) Cost of fuel.
(t) Water, cost of pumping.
(u) Cost of equipment.
(v) Cost of treatment.
(w) Interest and depreciation.
(x) Royalties and taxes.

Market:

(1) Quotation price.
(2) Smelter rate.
(3) Cost of transporting ore to smelter.
(4) Cost of transporting metals to market.
(5) Brokerage charges.
(6) Is the market free or restricted?
(7) Competition.
(8) Influence of increased production on prices.
(9) General market outlook.

Title:

Influence of the mining laws of the country on the industry.

Validity of title.

At the risk of being tedious I have tabulated these points, and will discuss them briefly later. This list might be lengthened indefinitely. Indeed I have seen printed lists of questions in book form for the use of the examining engineer which contained questions in regard to every conceivable matter in connection with a mine or prospect; but it seems to me that the use of such printed forms must lead to reports as stereotyped in form and conclusion as the form on which the data are recorded. For this reason the above list is only given as a guide and should be filled out, altered, or amplified to fill individual requirements and ideas.

Prospects of Ore—In considering (a), it should be kept in view that where there are no extralateral rights the property considered as a whole has the form of a prism of infinite depth, whose top is the exposed surface and whose sides are three or more planes (usually four) being common boundaries of the adjoining properties as in fig. No. 1. On the adjoining property to the south a shoot of ore has been opened on a vein striking north. This shoot pitches to the north and enters the prospect by the south bounding plane at depth. The ore has been mined up to the line of the prospect and has exposed a surface of the vein from (a) to (b) for sampling. It must be evident that such a surface, if it be accessible for sampling, is just as valuable a prospect of ore, other things being equal, as a like exposure on the surface. All exposures of ore should be sampled, measured and assayed just as carefully as would be done in examining a mine. There is no more reason for trusting to one's judgment for

*Mining Engineer, 103 Bay St., Toronto, Ont.

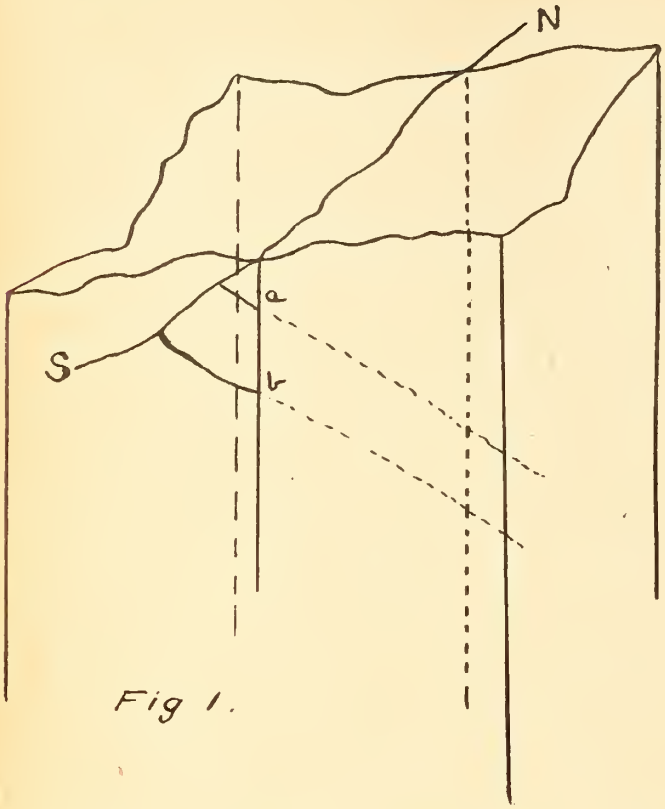

Fig 1.

the value of ore exposed in a prospect than in a mine. Yet this is often done. Before sampling a surface exposure it should be well cleaned of all surface dirt, and a wide deep groove cut in the solid ore. This groove should then be thoroughly cleaned out before taking a sample cut from the bottom. If the sample is cut from the natural surface it is liable to be too high on account of the concentration of valuable minerals in the small surface cracks or irregularities, or it may be too low on account of leaching out of part of the less valuable minerals from the immediate surface. One of the most common mistakes is to measure the outcrop on its horizontal width without taking account of the dip, and to assume that this is the true width of the vein.

(b) The preference which certain minerals have for certain formations is so well known that it needs no discussion.

(c) If a fissure cuts two formations and contains ore in one of them, it is quite likely to increase or decrease either in size or contained values on passing into the other. If the prospect is in a well developed district whose history in this respect is known, one may be able to foretell the change. If in a new district too much confidence must not be placed in comparisons with districts whose economic geology has already been worked out.

(d) In fig. 3, a section of a vein perpendicular to its strike is shown. It will be seen that the vein is faulted by a series of overthrust faults in a rather regular manner. However, as depth was attained, the fault planes were found to be closer together. After each section of the vein was worked out it was necessary to drive to the next section of ore and, of course, the dead work was charged to the development cost of the block so opened up. The first block paid handsomely, the second a little less, but it was found that no profit was derived from the fourth, although the vein was equally wide and of the same grade as in the former sections. This is but one instance of the way faulting may use up the profits of working an otherwise p able ore shoot.

(e) The considerations suggested by questio could not be profitably discussed here as they in the theory of the genesis of ore deposits—a fiel extensive to be even touched upon.

(f) The theory of secondary enrichment shoul be studied elsewhere. Its importance lies in the that where it occurs we have one of the few cas which we may hope for enrichment in depth. I sulphides are in their unaltered form on the su there is no reason to expect enrichment in dept cept in rare instances.

(g) Surface weathering without secondary en ment points to the surface enrichment of the vei a decrease of values in depth. This is due to the l ing out of some of the baser constituents of the leaving the part remaining in a more concent form. It also sets free the gold and silver, lea them in a state in which they may be more re amalgamated and, if they are to be smelted, they ready for smelting without roasting. Howev should be kept in mind that when we pass fron zone of surface weathering to the zone of primary phides, a change in treatment must be made. Su enrichment may not always be an advantage as it necessitate two distinct plants for the treatment o ore, and the interest and depreciation on the first offset the advantage gained by the richer ore.

(h) The effect of eruptives should be thoro studied.

(i) If the prospect is in a district already devel something may be learned on this point. If not, prophecies are as dangerous as prophesying o depth in a fissure devoid of mineral at the surfac der the same conditions.

(j) If a prospect is situated in a camp that h number of operating mines, many of the questions cussed under "prospects of ore" may be studied u the best conditions and much information gaine the economic geology of the district. In most the market conditions, cost of operation, and meta gical treatment may be determined with great a acy. In cases where the adjoining properties each worked up to their end lines nearly every f of risk may be eliminated. In many mines in the Superior copper region adjoining properties hav far determined conditions on a prospect that the agement was justified in designing and installing

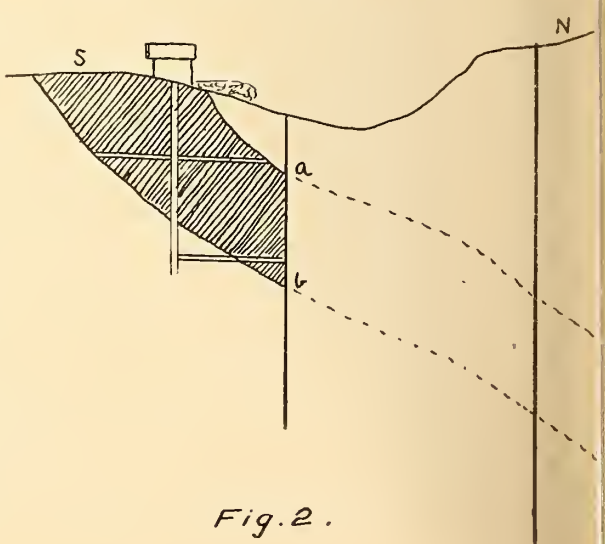

Fig. 2.

ve plant and machinery before the ground was ed. These cases are rare, however, and evidence surrounding properties should only be accepted great care and applied with judgment. In the ns of the inexperienced such evidence is highly erous. It is not seldom part of the stock-in-trade e fakir.

Metallurgy.

() A quartz ore containing a friable copper mineral may be so situated that it cannot be smelted owing to the impossibility of obtaining a base at a sufficiently low cost. It cannot be concentrated without too great a loss, and cannot be cyanided owing to the consumption of cyanide overbalancing the value of the gold or silver recovered. Again, the ore may be an intimate mixture of two metallic minerals having physical and chemical characteristics so similar that they cannot be separated economically. Of course, this discussion is based on the state of the art at the time the examination is made. Later improvements may make ores valuable that are to-day useless.

() If an ore is to be smelted at or near the mine the question of flux and fuel should receive the most careful consideration.

() In any case some limiting figures should be placed on the cost of mining and treatment. If this cannot be done, a report will be of little practical value.

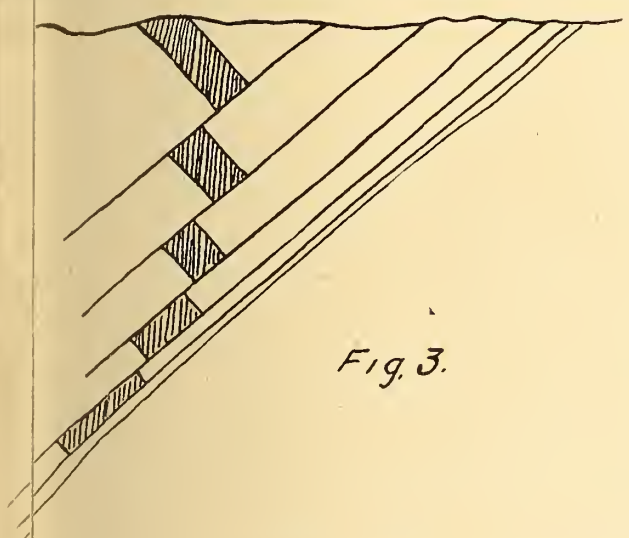

Fig. 3.

The final method of treatment cannot be determined, however, until the prospect has developed into a mine.

Cost of Operation:—This subject has been so exhaustively treated by Mr. Findlay in his admirable book that the different items need no discussion. If the prospect is surrounded by working mines and has the same character and grade of deposit as the surrounding mines, the cost may be taken from them. If the prospect is in a new district one should make as close an estimate as possible of the cost of working the ore, putting limiting values on each item as closely as may be determined, basing the estimate on the supposition that the ore will extend to a reasonable depth and have the same width and value. From this one may possibly arrive at the conclusion that the property is not workable at the time and under present conditions. Estimates made in this way are infinitely more valuable than mere guesses, and at least serve as a guide to the judgment.

Market

1 The price of gold is, of course, always fixed. The ation prices of copper, lead, and zinc, are usually given very closely by the technical journals since these metals enjoy an open market. All the other metals together with the non-metallic minerals have their prices fixed by private contract or mutual agreement and the prices quoted for them in the technical journals serve only as a guide. Before accepting a price on any of these minerals the market should be most carefully investigated.

2. Smelter rates should be obtained from as many smelters as possible. It should not be overlooked that distance is not always of first importance in determining smelter rates, but that desirable fluxing qualities may overrule the long haul.

3. Freight rates may, of course, be ascertained from the published schedules of the railroad companies, but should not always be accepted as the best rate obtainable. By negotiation the rate may at times be lowered considerably The new rate is then published and becomes the public rate.

4. The producer of a metal must always pay for transportation to the open market even if the metal is never actually taken there for sale.

5. A great deal of ore and many mineral products are sold through brokers and selling agencies. In the case of those minerals which are sold in a restricted market the brokerage may amount to a considerable sum. This fact should not be overlooked in estimating costs.

6. As stated under (1) minerals that are sold under private contract or in a restricted market should be the subject of a most searching investigation. If the engineer is not already familiar with and in close touch with the market he should either get the time for an investigation, or frankly state in his report that he is not prepared to report on the state of the market. Many otherwise good prospects fail because when the producing stage is reached it is found that there is no market for the product or that the actual price is much below the quoted price. Another common mistake is to estimate each metal at its full value while, as a matter of fact, the smelter may pay for only one or two of the metals contained in the ore. Indeed, I have seen all the metals in an ore estimated at their full value in a report, and when the ore was sold a penalty had to be paid on some of these metals.

7 and 8 Competition and the influence of new productions on price are closely associated. With the more common metals and those which are produced in large quantities, the addition of a new producer is not likely to affect the price much, but the effect of new sources of production on the price of a metal which is produced and used only in small quantities is likely to be disastrous unless the production is kept within due bounds, or unless some new use can be found for the metal.

9. Mr. Hoover in his book on the "Principles of Mining," treats of what he has called the base price of metals and discusses the fluctuations of metal prices. This chapter should be read.

Title.

When examining a prospect in a foreign country or in one where mining has not long been carried on, the engineer should make a careful study of the mining laws. The laws as regards royalties, taxes, and customs duties should be ascertained. In some countries, especially in the Latin Americas, there are many charges against the operation of properties that do not come under any of these heads, but that nevertheless must be paid.

The validity of title will, of course, be examined

closely by a local attorney, but it is always well for the engineer to examine the title himself.

General Considerations.

The amount of capital to be used in developing a prospect is of first importance. There is a minimum amount necessary. What this is, one can only estimate, but limiting values can usually be placed upon the amount. If the purchasers are not prepared to find this amount the property will probably be a failure no matter how good a prospect it may be.

When a prospect is discovered in a new district and under new geological conditions, too much is often made of comparisons with older districts. Suppose that a mineral has been mined in four properties, A. B. C. and D, in four different parts of the world, and that the geological conditions at A, B, and C, are similar, but quite different at D. Now, if all the properties have been operating for some time, everyone accepts the difference in conditions between the first three properties and the fourth without comment. But suppose A, B, and C have been operated under similar conditions for years and let D be discovered under different conditions; then the impression may immediately arise that it cannot be of any value. This is a very common fallacy. But, while comparisons with older districts are of the greatest value as guides, an occurrence under new conditions should never be condemned on comparisons only.

In any one prospect a great many of the points touched upon will be found to be of little or no importance. However, each must be gone over and those of no importance may be quickly eliminated from the enquiry and the attention concentrated on those remaining. I would suggest that numerous sketches and careful notes of all the above points be made in the field note book. All this information need not go into the report but may become invaluable at some future time. Often after the report is made the engineer may be employed to direct the work, and copious notes and sketches may enable him to initiate operations without a second trip to the property.

It must be left to the common sense and judgment of the engineer as to what material should go into a report, but one should always remember that a report will be read by two classes of people, the layman and the engineer. The first desires a short and lucid statement of the main facts with a clear cut statement of the conclusion arrived at. The engineer, in addition to this, wishes to have the details before him so that he may decide for himself whether the conclusions are justified in the premises.

To fulfil the needs of each class to whom the report will be presented it is usually best to divide the re into two parts, first the general report and conclu and second an appendix containing the details, sisting of measurements, lists of assays, detail des tion of geology and outcrops, estimates of costs, fr rates, markets, etc., or such of these matters as a importance. The report should as a rule conta map of the property, showing the outcrop, assays, geology. If the geology or development of the rounding properties has had any bearing on the clusions arrived at, a map showing these feat should be included, if necessary to a proper un standing of the facts.

A few engineers try to protect themselves by lea out the details, so preventing any criticism of the clusions; but if the prospect is developed and fail fulfil its promise, their lack of nerve receives its ward, for then they are denied the opportunity to sent the details which they should have set out in original report.

When examining a prospect in a district unfam to the engineer, he should always obtain local ad if it can be had. Do not be too ready to cond what is new to you in mining practice, when it stood the test of time. Although it may appear t wasteful, careful study may show you that it is survival of the fittest under the ruling conditions. obtaining local advice you may get a satisfactory planation of what seems bad practice and save you from the mistake of promising economies which cannot fulfil later.

In these days of changing conditions too much s to be made of codes of professional ethics. If one a sound conscience he will have no need of a con tional code of ethics. If he has not this conscie there is no code of ethics he will not break. The rule that should always be followed is to disclos your report and to your principals your true posi in relation to a property. Anything that canno set out there should not be done.

In conclusion, I would suggest that one should be in a hurry when examining a property even be a prospect. Spend some time on a property (warrants it) and by turning the facts over in mind with their bearing on each other, gradually rive at a cool, deliberate judgment by a more or unconscious integration of all the facts obtain remembering that one's judgment of a prospect not always be correct and that your client is pay you to commit yourself definitely one way or the ot He should not, and likely will not, be satisfied wi report that does not commit the engineer.

OUR EUROPEAN LETTER

Mining shares quiet — Oil descriptions more active— Petroleum developements in Galicia, Roumania, Maikop, Persia, and Eastern Siberia — London Organizing an oil exchange — Many new companies Floated — Electric winding developments in British colonies — An interesting plant — The Waihi all-sliming process and tall tank treatment — Why the Rand is out of favour — Northern Nigerian tin a growing industry.

(Exclusive correspondence of CANADIAN MINING JOURNAL.)

London, April 21st, 1911.

Business in mines on the London Stock Exchange continues small and the speculative account for the rise is not large. Throughout the greater part of present year the market in South African mi shares has been persistently dull and at the end March it became acutely weak as the result of fi cial difficulties on the Paris Bourse. Whatever covery has taken place recently has been largely bear covering. Rhodesian shares keep very stagn but Russian gold mining shares have been rather m active. Tin shares have been fairly firm and a tinual stream of new tin flotations proceeds.

Oil is another fairly active spot although the April spurt of activity soon petered out. Here ag new companies are frequent. The oil trade outl in fact, is good and one of the most notable incid

the steady progress that is being made in the utilization of oil for power purposes either in the form of liquid fuel or applied direct in oil engines. The world's production of oil has more than doubled in the last ten years but all the same new areas are being continually opened out. Good oil lands in Galicia are being extensively sought after. One German group, for example, has expended between $150,000 and $200,000 in purchasing small properties in order to consolidate its interests, although only a small amount of drilling has so far been done in their particular district. The English producing companies with plenty of reserve lands for development are in a very healthy position. The Austrian Government intends largely to increase the use of oil fuel on State railways, and Waclaw-Wolski, president of the Crude Oil Producers' Union of Galicia, gave it as his opinion on April 17th that the present price of crude oil would undergo a small rise in the near future.

At a recent lecture by Professor Szainochau it was urged that the theory of the animal origin of petroleum allows of an easy calculation of the immense underground stores of petroleum to be extracted in Galicia. Taking the area of the menelithic slates to be equal to only 1,000 kilometres, and the thickness of the stratum of rocks to be only 50 metres, we have thus a mass of menelithic rock of 50,000,000,000 cubic metres. Admitting, again, the average specific gravity of the rock is equal to 1.2, the total weight of the rock must be not less than 60,000,000,000 tons, which, taking its contents in bituminous matter as equal to only 1 per cent., would give a total of 600,000,000 tons of bitumen. Assuming these bituminous matters to have given origin to only 50 per cent. of petroleum, we attain the lowest estimate of the Galician petroleum wealth as equal to 300,000,000 tons, of which only 12,500,000 tons have been extracted during the last fifty years.

The total production of petroleum in Galicia during last year was 1,762,560 tons, 91.6 per cent. of this being produced on the Tustanowice and Boryslaw fields. Following upon years of uninterrupted increase these figures show a decrease on the previous year—a decrease which would have been larger had it not been for the newer smaller fields in the east and west of Galicia. Activity is also reported amongst Roumanian producers, who are benefitting by the abolition of that portion of the taxes on kerosene known as the communal fund, which is levied at the rate of five francs per 100 kilogrammes. This is considered to be the first step to the total abolition of taxes upon kerosene in Roumania.

From as far away as the Eastern Siberian coast comes other interesting oil information. Engineer Preskuriakoff recently delivered a lecture before the Russia Technical Society, on his investigation during last summer of the petroliferous areas on the east shores of the Isle of Sakhalin. The lecturer gave a short physico-geographical description of the Isle, based on data supplied by scientific expeditions during the last three years, supplemented by his own observations during the four summer months of 1910. The petroleum and coal wealth of the Island of Sakhalin, said the author, was practically inexhaustible, and would be sufficient to supply the whole world with fuel for centuries. A rather large order this!

The Maikop district in the south of Russia is working hard upon its pipe line connections through some of which already oil has commenced to flow. Those Maikop companies that are already producing and have stocks of oil are now in a position to put their product on the market and earn profits. A new Russian law is reported to the effect that foreign companies in the Maikop district must employ only Russian subjects for their technical staffs and as managers of their properties.

From Persia comes the news of proved petroleum. Exceptionally rich are reported to be the basins of the rivers Ab-i-Dizi and Karun and the Isle of Kishma. In these places oil spurts from the earth in large quantities and almost all the deposits are situated near to the sea or a navigable river.

To organize the oil business of London better it is proposed to form an oil exchange which will bring into close touch producers, refiners, carriers, distributers, merchants, company promoters, brokers, underwriters, engineers, and promoters.

Recent oil flotations here include such varied emissions as the following: Franco-British Oil Trust, capital one million and a quarter dollars; Venezuelan Oilfields Exploration, capital $787,500; Central Ohio Oilfields, capital $800,000; Kuban Black Sea Oilfields, capital $1,500,000; Californian Amalgamated Oil, capital, $1,750,000; Caucasus Domains, capital $2,500,000; Asiatic Petroleum Company of Egypt, capital $1,000,000; and West Coast (of South America) Oilfield, capital $500,000. These were all registered within the first fortnight of April.

Colliery owners and colliery engineers in Great Britain are naturally increasingly interested in electric winding, and an installation just put down in the South Kenmuir colliery in Scotland is expected to be the beginning of a series of important changes in British colliery districts. The advent of electric winding here has been hastened by the appearance of the power companies which supply electricity at rates usually lower than the consumers can generate it for themselves. The winding gear at the South Kenmuir pits is designed for winding eventually from a depth of 160 fathoms, although at present it is only working from the 90 fathoms' level. Each cage carries two hutches with a total of 1,904 pounds of coal, the empty hutches being lowered in the other cage, and as a winding schedule of 65 winds per minute can be obtained, the gear is capable of dealing with 55 tons (of 2,240 pounds each) of coal per hour. The main winding drum is of the spiro-conical type, in which at the commencement of the wind the ascending rope is on a part of the drum which has a diameter approximating 5 feet, while the descending rope is on the centre of the drum, whose diameter is 10 feet. This arrangement has the effect of minimizing the effort required from the electrical plant during the period of acceleration, the rope being transferred to the larger diameter towards the end of the acceleration period by a cast iron spiral formed in the drum check. The electrical equipment involves the use of a motor generator which converts the three-phase alternating current taken from the power supply company to continuous current, which is found to be more suitable for driving two motors attached to the gear. The motor generator not only performs this conversion but is so designed that the characteristics of the continuous coal supply are exactly suited to the demands of the gear motors.

The actual control of the gear is manipulated by means of a regulator in the field circuit of the motor generator and by a reversing switch in the gear motor circuit, these two switches being electrically interlocked in such a way as to make it necessary that power should be removed from the motors and the brake applied before they can be reversed. A mag-

netically operated brake is provided, the action of which is controlled by the electrical circuits in such a way that the brake is applied and the cages are brought to rest in response to the movement of the controller or to the opening of the limit switches as well as to any interruption to the main power supply. A depth indicator geared to the winding drum is provided to show the position of the cage and to trip the overwinding switches in the event of the man in charge not attending to the indicator and bringing the controller to the stop position sufficiently early. Although it is not necessary in the regular manipulation of the gear, there is an additional brake having a foot pedal and a trip coil for directly applying it if the supply from the mains should fail. A series of tests have been made, from which it is possible to estimate the cost of winding. The maximum demand of power from the mains does not exceed 120 kilowatts, and the number of units taken when making 65 winds per hour is equivalent to 1.4 unit per ton of coal raised. Assuming that electrical energy can be purchased at the rate of 1½ cents per unit, the cost for power of winding coal from this depth is slightly less than 2.2 cents per ton, a figure which will compare very favourably with the cost of winding by steam, especially in view of the fact that only one man is required and that he only needs to attend during actual winding hours.

Interesting accounts are being published here regarding the remarkable results obtained at the Waihi Grand Junction mine of New Zealand by the all-slimming process and tall tank treatment. Considering that the ore treated is very refractory, and contains a large proportion of silver associated with 8 to 10 per cent. of sulphide-pyrite, saphalerite, chalcopyrite, with arsenic and antimony, a total working cost of under five dollars per ton of 2,240 pounds, after allowing one dollar per ton for ore development working on a 40-stamp basis, is an exeellent result. The results are taken from the actual working of the plant over a period of six months, from January to June, 1910. One authority here holds that if such results on such a difficult ore can be obtained as exists in this mine, the same process, if applied to the simple ores of the Rand, would produce a revolution and allow costs to be reduced by several shillings per ton. With all the experience of the Rand, evidently mueh has still to be learned and mueh unlearned.

With regard to the Rand, as I have before indicated, the market has a sagging character upon which most of the newspapers here from the "Times" downward have been giving their views. Perhaps the truest view of the present dulness in Kaffir shares is that a lower level of prices at the present time suits the book of the big mining groups. Working on very excellent principles the mining houses take in stoek when prices are low and off-load when they are above intrinsic merits. Most of the big Rand mining shares are at about two-thirds the price they stood at in 1909. But they apparently have got to be lower still before the public can be attracted in. The Rand eight hours' day and the miners' phthisis compensation bills have helped those who wanted to bring the market back and there has been a great deal of exaggeration about the results of these measures.

The fact also that Wernher Beit and Company are disposing of their interests in the Central Mining and Investment Company and that the Goldfields people are investing largely in the United States are things that do not tend to encourage the investor here. Neither does the suggestion that the Johannesburg Stoek Exchange may be forced to close its doors. Furthermore, labour is decidedly more expensive on the Rand partly owing to the high cost of recruiting, and general working costs are abnormally high at many well known mines.

Against all these things, however, there is the solid fact that according to one authority there is still ten thousand million dollars' worth of gold to be won on the Rand, that labour is increasing in quality, with the result that good effects should be felt by May, and finally, that the experiments with small rock drills are so satisfactory that hopes are expressed by one of the leading groups that it may be possible by the end of this year to do away entirely with native labour in drilling.

The new tin mining district of Northern Nigeria continues to attract attention, and while there is no boom in Nigerian tin shares, every week that passes sees the registration of two or three new companies to work there. The existence of tin in Bauchi, in considerable quantities, became a recognized fact at the close of 1909, and the evident possibilities of great development are attracting to that district a large number of prospectors and mining engineers. The stanniferous area is very wide and appears to be much more extensive than was at first believed. Some of the alluvial deposits are so rich that they may be profitably worked even under great difficulties, and the prospects of developing our important mining industry are very promising.

The position of the tin market at the present time appears to be that whilst the world's consumption has increased by 1½ per cent., the world's production has decreased by 4½ per cent. so far as last year was concerned It also appears that the production from the older tin fields is likely to decrease in quantity in the future. Even with the primitive methods of winning tin in Northern Nigeria the cost of tin oxide won in the Bauchi province delivered in London does not exceed $250 per ton, whilst the prices ruling for tin oxide from that field at the present time are somewhere about $600 per ton.

The Colonial Government is building a railway from Rigachiku to Leri, which was at the foot of the tin field, without calling upon any of the mining companies for financial guarantees, the simple stipulation being that the companies shall give the railway the carriage at an agreed rate both to and from the field for a period of five years. The machinery, plant, and requisites for this valuable railway extension are to go out to the West Coast by about August of this year. The estimated cost of construction — $15,000 per mile —will make it the cheapest line ever constructed in tropical Africa. Life and property are now as safe in Northern Nigeria as in any other of the African protectorates, although the country has an area exceeding 250,000 square miles and a native population of about eight millions.

It has been announced that the coal lands in Alberta of the Consolidated Coal Fields, Limited, situated miles southwest of Bickerdike on the Brazeau branch of the Grand Trunk Pacific Railway, will be extensively developed during the ensuing summer. Throughout the winter men have been engaged in laying out the lands and preparing for sinking shafts. The area of the property is stated to be 7,600 acres, surveyed last year. Coal from this property will, it is claimed, be the first to reach market from the Brazeau district.

SOME NOTES ON SAMPLING AS PRACTISED ON THE RAND.

(Written for the Canadian Mining Journal by Robert W. Thompson.)*

n view of the likelihood of a gold camp of conerable merit and permanence being developed in ario, it may not be out of place to outline the gen- method of sampling as followed on the large proing gold mines of the Transvaal.

he object of the sampling department is to keep management posted up to date on the values as nd in the development work, drifts, winzes, cross- , etc., and also along the faces of the working stopes.

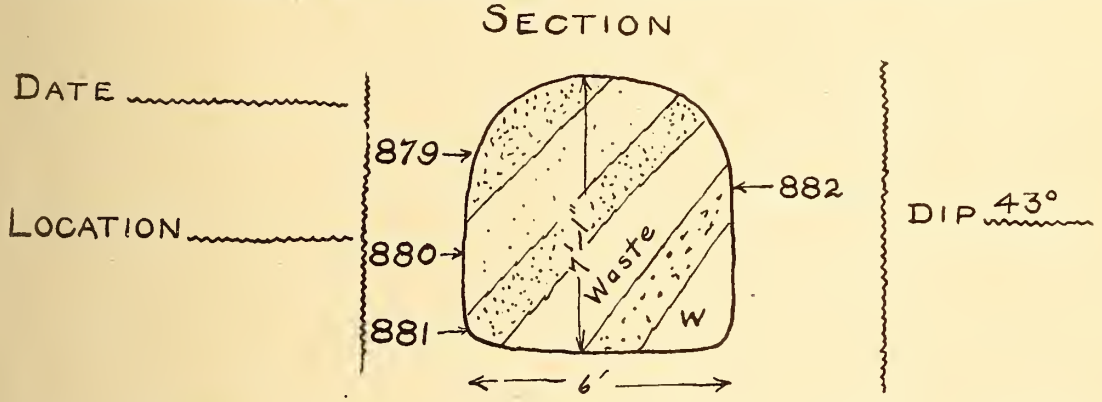
ach sampler has a section of the mine for the pling of which he is responsible.

he sampling house is equipped with drying fur-, electrically driven crushers, and grinders, pan- troughs or tubs, mixing tables, ordinary grocers' s, and shelves for storing discards.

e whole of each individual sample is ground to a 60 mesh sieve before quartering for panning and samples. The crushing and grinding is attended a native "boy" who returns the ground sample e sack in which it came from the mine with the earing the sampler's initials and the sample number.

is is thoroughly mixed by rolling on a piece of ican cloth. The panning and assay samples are selected and the discard filed away until the returns from the assay office are received, when if these are found to harmonize with the panning result the discard is thrown away. If the panning and assay returns do not agree a fresh portion for each is taken from the discard for a check, and the error located.

In development drifts it is customary to take a section across the face after each round. Some managers prefer taking samples at regular intervals of from five to ten feet along the walls. The former method is preferable as more accurate results can be secured and a better conception of the changes in character of the reef obtained by working on a clean face than by working on the dirty walls of the drift.



SAMPLE Nº	WIDTH	REMARKS	PAN	ASSAY
879	14"+	Scattered Pebbles	1 dwt	1½ dwt
880	12"	"	2 "	3 "
881	9"	Well defined Reef	16 "	23 "
Waste	25"			
882	11"	Heavily Mineralized	22 "	37 "
Waste	15"+			
MIXED PAN			9 dwt	14·6 dwt

Figure 1.

The distance of the section from the nearest survey peg is accurately measured so that the results can be platted on the assay plan.

Samples are taken across the face, starting at upper part of reef exposed and working towards the footwall, or vice versa, as the sampler prefers.

The width over which each sample is taken depends on the appearance of the reef and the discretion of the sampler, usually not more than twelve to fifteen inches is covered by any one sample.

A typical section as it might appear, with accompanying notes in a sampler's notebook, is given in fig. 1.

*ining Engineer, 14 West Charles St., Toronto.

A portion of each individual sample after drying and grinding as above described, is panned by the sampler and the result entered in his notebook after the corresponding sample number. Another portion is sent to the assay office and the returns entered in a similar manner. As a check on the pannings as well as on the assay returns, a "mixed pan" is made up by taking an amount from each sample proportional to the width over which the sample was taken. In the example, fig. 1, this would be made up as follows:

From sample 879 take 14 ounces.
From sample 880 take 12 ounces.
From sample 881 take 9 ounces.
From sample 882 take 11 ounces.

These are thoroughly mixed and a portion panned. The result from this panning should agree with the average worked out from the individual pannings. Also the assay returns from this "mixed pan" should agree with the average worked out from the individual assay returns. When it is found that the panning and assay returns check up, the final results are entered up in the sampling ledger with a section as shown in fig. 1. The stoping width and values are also worked out and entered in the ledger. In the example taken, that part of the reef covered by samples 879 and 880 being below pay value, would not be included in the stoping width. This latter would be: Reef 9 inches, waste 25 inches, reef 11 inches, equals stoping width 45 inches, and the average value equals pan 8.6 dwts., assay 13.6 dwts. Again, the milling width and value are calculated from these results and entered up in a separate column. In this case about 12 inches of the waste rock would be fair sorting, leaving a milling width of 33 inches and a milling value of pan 11.7 dwts., assay 18.5 dwts.

In entering up the results on the assay plan the average value of the pay reef is given and the width of the included waste rock noted. The section under consideration would be platted on the plan as follows: W 25 R 20 P 19.3 A 30.7, meaning that there is 20 inches of pay reef panning 19.3 dwts, assaying 30.7 dwts., and having included waste rock of 25 inches.

In sampling stopes the same method is followed except that the "mixed pan" is not used. Sections are taken along the stope face at regular intervals of from five to ten feet. The results are entered in the stope sample book in detail and the final result obtained for each section is platted in its proper position on the plan of the stope as surveyed at that date. From these data the average stope value is worked out.

Sampling records of winzes, raises, and cross-cuts are kept in a separate ledger.

Steamboat Mountain, B.C.

The "Standard," published at Kamloops, British Columbia, on April 7th printed an article headed "Wildcat Staking," in which the opinion of a visitor to Steamboat Mountain district, which is being much "boomed" in Vancouver, B.C., is quoted to the effect that irresponsible staking is very prevalent and that unless it shall be discontinued it will work harm to the whole of this new prospecting camp. The statement is made that there are men in the district staking mineral claims, being paid a salary for doing so, and that the object of some seems to be only to stake claims and sell them for $100 each, if more be not c tainable. It is alleged that up to April 1 there h been about 700 claims recorded and that on one d in March 40 records were taken out. The significa comment is made that those who know what thin are like in Steamboat Mountain district and t amount of snow there is in the hills, will realize t conditions under which staking must have been do

Our British Columbia correspondent informs us th while specimen assays have indicated that ore c taining comparatively high value is found in the d tract, there has not yet been done sufficient develo ment to demonstrate that payable mines will be fou there. The deep snow of the winter has prevent much effective work being done on the claims, so is yet quite premature to conclude that there is wa rant for many statements to which publicity has be given, and which may yet, and probably will, be fou much exaggerated. One extreme case of trying to cite the public in this connection is that of a two-pa advertisement in one of the Vancouver daily new papers, the advertisers seemingly having little rega for anything but how to get hold of the dollars those foolish enough to be induced to part with th money for very small pieces of land platted as to lots in a mountainous district as yet altogether un veloped and the future of which is, and pending s eral years' steady development must remain, quite u certain. Some illustrations, seemingly intended to m lead, suggest that mining and milling has reached stage far beyond what the present situation is in t camp. It will be well, therefore, for those whose tention has been attracted by "boom" notices Steamboat Mountain, in Yale district of British C umbia, to make careful enquiry before putting mon into it. This is not saying that the camp will n eventually be a good one; only that as yet it is qu unproved, and that many very extravagant statemen concerning its value have been and are being giv publicity, against which it is desirable to warn t public.

Keekeek Lake Region

Through the courtesy of Mr. Theo Denis, Superintendent of Mines, Que., the CANADIAN MINING JOURN is enabled to publish the latest map of the Keeke Lake region. It will be noticed that considerable sta ing of gold claims has already been done. A glan at the map shows many names of mining men iden fied with Cobalt and Porcupine. Amongst these ar P. A. Robbins, E. J. Darragh, C. A. Foster, B. Crawfo M. F. Fairlie, Alex. Gillies, W. H. Reamsbottom, Shields, T. J. Renwick, N. Bilsky, and many others.

As Keekeek Lake is in Pontiac County, Quebec, ne the Ontario border, there will probably be a conside able number of prospectors ready and willing to ha their attention diverted to a new land of promise.

The map reproduced herewith shows the number claims staked up to April 10. Only a few claims alo the lake were staked before snow fell.

During the coming summer Dr. J. A. Bancroft, McGill, and Mr. Valequette are to work over the d trict for the Quebec Mines Branch.

MARITIME OILFIELDS, LIMITED

The following account of the second ordinary general meeting of Maritime Oilfields, Ltd., held recently in Glasgow, is reprinted from The Financial Times, of London, England. To many of our readers the facts here set forth will come as a surprise. It is noteworthy that New Brunswick's chief industrial centre is soon to have a supply of excellent natural gas. 37,500,000 cubic feet of gas per day can now be supplied by the company. The details as presented hereunder are worth reading:—

The chairman said the company's financial position was strengthened during the year by the increase of capital to £100,000 and the issue of 30,000 ordinary shares, upon which 7s. 6d. per share had been called up; 29,000 ordinary shares are held in reserve. During the year Messrs. Claud A. Allan and William Walker had joined the board. After dealing with the accounts the chairman reminded the shareholders that when they last met together in general meeting test wells Nos. 3 and 5 had proved, in addition to high-grade oil, the existence of natural gas in large quantities upon its property in New Brunswick, Canada, and having in view the possibility of immediately turning the latter product to profitable account, it was decided to concentrate all work upon natural gas development on the anticlinal at Stony Creek, in Albert County, upon which these wells had been drilled. Accordingly, development work was carried on energetically and systematically upon this "gas pool," and excellent progress was made, with the result that during the financial year under review eight further wells were sunk at Stony Creek. Of these, two had to be abandoned on account of becoming crooked before the third, or most prolific, group of oil and gas sands was struck, but all of the remaining wells proved exceptionally fine gas wells, with an aggregate yield of 9½ million cubic feet of gas per day. These gas wells are all oil producers, some indeed promising excellently, and were it not for the much greater relative value of their gas yields, would be treated as oil wells. Excellent as these results were, still more remarkable developments took place immediately after the close of the financial year, and in October and November three large gas wells were brought in (well No. 14—12,000,000 cubic feet per day; well No. 15—6,500,000 cubic feet per day; and well No. 16—9,500,000 cubic feet per day), with a combined gas yield of 28,000,000 cubic feet per day. Other wells are being completed or are in course of drilling.

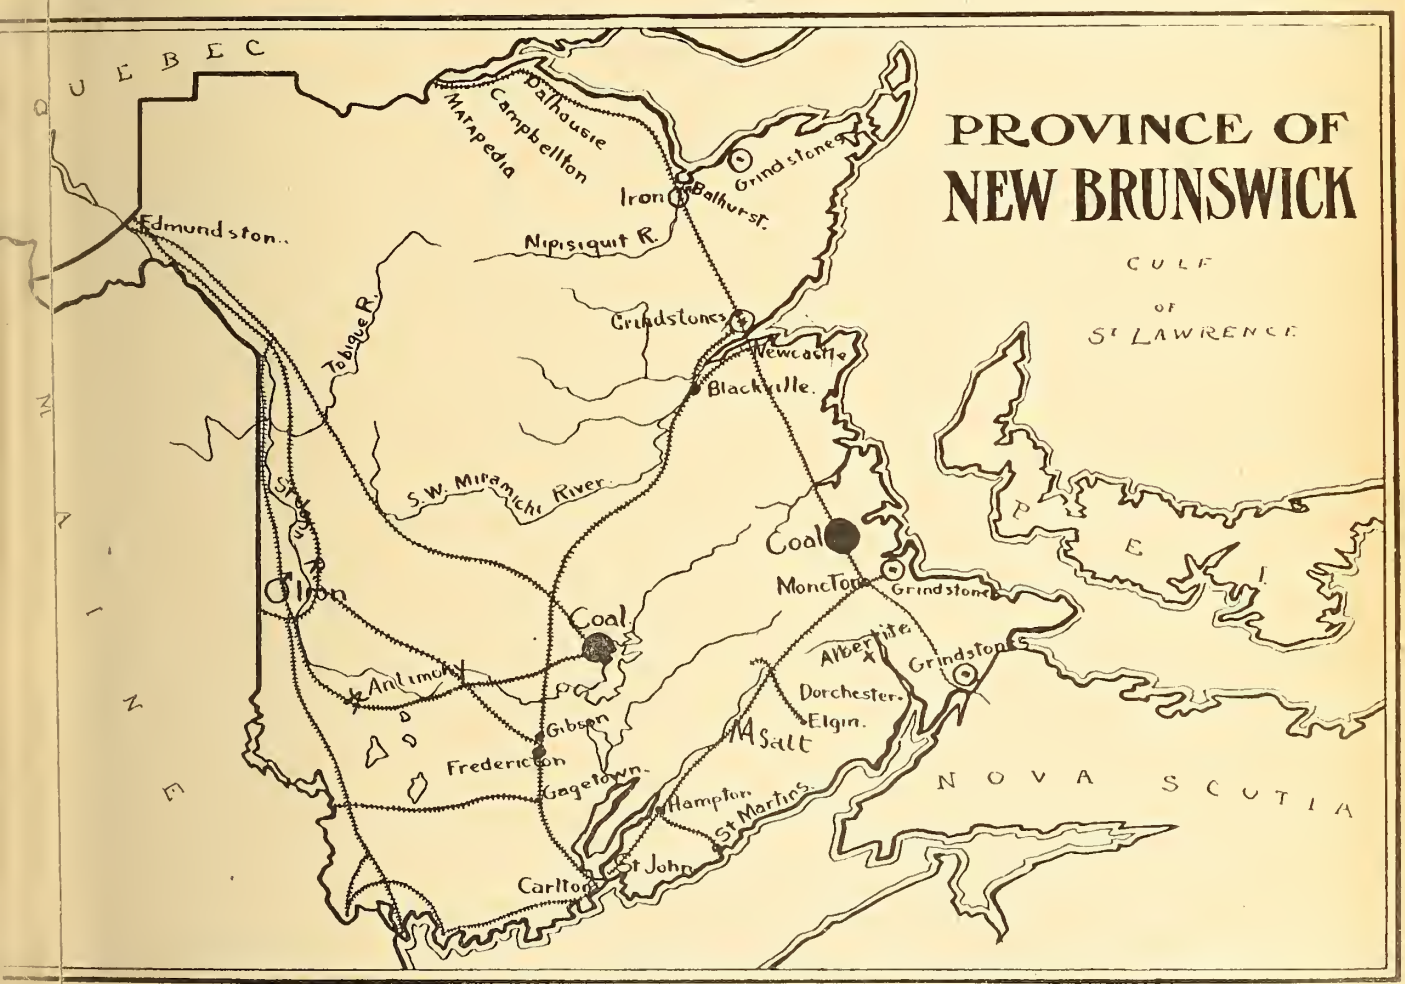
The Company's Property.

The company had now 13 productive gas and oil wells, yielding a total measured flow of 37,500,000 cubic feet of gas per day and a considerable flow of oil, which latter is impossible of measurement owing to the necessity of shutting in the wells under the great gas pressure existing (as high as 600 pounds per square inch), but in certain wells which it was possible to "shoot," initial oil flows ranged up to 60 barrels per day. The development work on the Stony Creek "gas and oil pool" had now thoroughly proved a length along the anticlinal of over 1½ miles and a breadth of over half a mile. The successive wells westwards have proved to be increasingly valuable, and the geological conditions continue favourable. In accordance with the best natural gas practice, the company has sunk only one well per 30 to 40 acres. As the greatest portion of the area developed is oil-bearing also, and as oil-well practice calls for one well per 5 acres or le there is room for over 100 additional oil wells to sunk on the area already developed when the ti comes to treat this as an oil-field. The Albert Coun anticlinals had been traced over 40 miles west, whe natural gas springs occur, and there were thus gre possibilities in this southern section of the company area. The three groups of productive oil and g sands tested at Stony Creek had proved persistent character and extent as gas and oil-bearing. Ea group contained up to six distinct sands—individu sands varying from 2 feet to 100 feet in thickness and the maximum aggregate thickness of sands in a one well exceeded 250 feet. A still deeper group of sands as yet untested at Stony Creek was known exist, whilst the total thickness of the oil-bearing f mation is still unknown, but has been proved to ceed 3,000 feet. The natural gas had been a source very great economy in the company's operations all power, heat, and light purposes, in connection w which about 60,000,000 cubic feet of gas were c sumed during the year; indeed, since gas was fi struck, the company has used for its own purposes less than 100,000,000 cubic feet. The company v now in a position to run three strings of tools conti ously during the current year. Several additional r have also been constructed and a large amount spare material has been purchased in order to sec the best working results. The company's developme have attracted considerable attention throughout N Brunswick and other parts of Canada, and in oil a gas circles in U.S.A. A large number of influen people had visited the property and were much pressed by the results attained. Two directors, Dr. Hope Henderson and Mr. L. A. McGeoch, whilst New Brunswick, took the opportunity of paying a v to the property.

Value of Natural Gas.

In dealing with the question of the value of natu gas the chairman said that it was one of the most portant products in North America, where the gro of the industry had been phenomenal, and it now ra amongst the great industries of the age. In the Uni States natural gas companies' securities are regar as first-class investments, the total capital invested this business approximates $225,000,000, and last ye production of gas was valued at $57,000,000. Natu gas is used for all household purposes—heating, co ing, lighting, etc.—wherever it is available, owing its extreme convenience and economy. The demand these purposes is invariably greater than the sup and in the United States the price of natural ga rising rapidly. For manufacturing purposes natu gas, as is well known, has had an enormous effect the rise of industrial centres, such as Pittsburg. tural gas is eagerly sought after for the productio cheap power, and for fuel in iron and steel industr glass making, cement making, etc. The question a the life of gas wells, which, next to that of markets gas, is most frequently asked, had to be very caref considered in opening up a new field. He was gla say that the Stony Creek wells, from prolonged t had proved good "stayers," and that geological ditions also warranted the confident belief that t gas wells would prove long-lived. Gas wells in United States, in similar sands, have proved, with per care and management, to have great staying q

, and wells of 20 to 30 years of age are not rare, lst it is held that 40 or 45 years is by no means the it in certain districts. For the purposes of the com- y's estimates, however, the soundest and most con- vative natural gas practice had been adopted, and mates were based upon 10 per cent. of the mea- ued yield of the wells as an average effective delivery r an extended period. Abundant markets for na- al gas exist in this long-settled country, within easy ing distance of present and possible future devel- ents. It is estimated that the present demand for estic and industrial purposes within the towns ex- ding from the port of St. John on the west to Sack- e on the east amounts to £500,000 in value per an- . The city of Moncton, an important and growing way and industrial centre, lies about 8½ miles due



of the gas wells, and the company had, through edium of Acadia Syndicate, Ltd., entered into a factory arrangement with Moncton Tramways, ricity & Gas Company, Ltd., for the supply of al gas to the city. It was estimated that the de- for natural gas for domestic and manufacturing ses in Moncton would be at least 1,000,000,000 feet per annum, and it was hoped that the Monc- ompany's gas installation would be completed by utumn, when Maritime Oilfields, Ltd., should be- a regular profit-earning institution from this one alone. During the year applications had been ved for the purchase of the company's oil output extended periods, but the board considered it pre- re to enter into any such arrangements. The poli- tlined in last year's report had been adhered to into consideration, hold that it is important to secure a large amount of working capital by the flotation of a large company whenever a favourable opportunity oc- curs. They believe that the very favourable results already achieved fully justify them in appealing to the public. Drilling operations will be carried on as usual during this year until other arrangements are made. The chairman referred in terms of high appre- ciation to the services of the field manager, Mr. Oren P. Boggs, and the staff in New Brunswick.

The reports were adopted.

Mr. L. A. McGeoch, in referring to his visit to the company's property, said he had nothing to add to the speech of the chairman, which covered the ground very fully. He was much struck with the scope of the field development work, and the thorough and busi-

nesslike manner in which it was carried on in the face of difficulties which were not always realized at home. He considered it an extraordinary thing that only two or three scout wells had been necessary to locate the anticlinal upon which the company was obtaining its results. The great pressure of the gas and its terrific roar made him realize the amount of gas which existed there. He referred to the local confidence in the future of the field, and to the possibilities in store f the city of Moncton, into which the gas would be i troduced this year.

The retiring directors, Messrs. Claud A. Allan, Wi liam Walker, and W. Hope Henderson, were re-electe The auditors were reappointed. A vote of thanks t the chairman brought the proceedings to a close.

Gold Mining in Western Ontario, A Lesson from Mining History.

(Written for the CANADIAN MINING JOURNAL by W. E. H. Carter.)*

Illustrations furnished through courtesy of the Ontari o Bureau of Mines.

The great activity in the hunt for gold in the Porcupine area and adjacent fields, brings forcibly to the writer's mind another gold-bearing region in this province, and also the fact that there is a psychological element in the growth and success of any mining camp, probably most pronounced in the case of gold. Unless this element be understood one may look in vain for adequate causes for the unfortunate subsidence into obscurity of certain mining fields, once the cynosure of the eyes of the mining world. As regards Western Ontario, this fact never was appreciated.

It is easier to look back and see the mistakes made, than to recognize them in the making. In the first case one sums the subject up for himself. In the second, there are endless interests in the field, each working out his mining problem in the way in which each thinks lies the salvation of his pocket. That the lining of his pocket should be derived from actual dividends earned by the mine has almost always been the last object provided for.

There is no desire on the writer's part to draw comparisons between past and present, for such comparisons do little good. Only with the advancement in knowledge by the public of the legitimate business side of mining and with a growing appreciation of the evils attending the exploitation of any new field, will the real value of any mining camp be properly and thoroughly determined.

Our experiences in the past six or seven years with mines almost at the doors of residents in Central Canada, as for instance in the Cobalt and outlying mining camps, have been manifold and without doubt are already exercising a beneficial effect in the development of the most recent discoveries of gold in the Porcupine areas. Had it been any mineral other than gold, which in a new and apparently deserving field always has awakened afresh the interest of the world, no such general speculative and investing interest as is already in evidence would have resulted.

In the April issue of the Mining Magazine (London) is an article entitled "Mining Speculation," signed by "A Director," of whom the editor speaks as "a financier not without authority." These remarks amongst other things put in words a truth that we have probably all realized dimly before, to the effect that "The speculator is a more important factor in mining finance than the investor." The speculator is a psychologist in operation if ever there was one, and therefore let us not now tax his credulity to too great a extent by asking his financial aid in any and eve forty acres of ground in the north country. If tho who make it their business to sell mining property the company promoter (not, of course, the prospect offering his own claim, for he is too strongly biassed will only take the trouble to secure ground which the report of a technically and morally qualified me ber of the mining engineering profession has a fa chance of success with development., there will many less failures, the public interest will be retain long enough to provide working capital for those pr perties which are gradually proving themselves dese ing and the speculator will in the end give place to t investor. Indeed the speculator will himself oft enough become the investor.

As a community we are, I believe, much better t ted than we were a few years ago to appreciate th "mining engineering is now one of the scientific pr fessions, a high standard of technical knowledge demanded and is forthcoming and, what is of equ importance, a high code of professional conduct a etiquette has been set up and is for the most part o served." To quote further, "In all respects the co trasts between the conditions to-day and those obta ing ten years ago is striking and unmistakable."

In my opinion, formed by actual contact over period of five years, first as operating engineer, a later as Inspector of Mines for this province, it was t utter carelessness of those who put up the mon speculator and investor alike, that finally, about t beginning of the last decade, brought to naught t Western Ontario gold areas in spite of the many veloped and finely equipped mines, a number of wh had for some years been producers.

Gold was first discovered in the Lake of the Wo country in 1883. Sporadic attempts at mining c tinued only for a year, or two. Soon, however, fr discoveries gave a renewed impetus and operati were steadily enlarged extending to practically ev accessible part of the western end of the provi The height of activity was reached in 1897, after wh the reaction set in, inevitable after the abuse of codes of mining business, and the industry gradu lost ground. Even then a good deal of irregular more or less successful prospecting was done, for til as late as 1900 new gold-bearing territory was a ed, the last land of promise being Sturgeon Lake,

*Mining engineer, 85 Front St. East, Toronto, Ont.

s north of Ignace on the C.P.R., and the Eagle
area, south of Eagle Lake station on the same
way.
the numerous gold properties in Ontario, 34 had,
e year 1901, stamp-mills ranging in size from 2

Golden Star, and Olive mines. The following table gives the number of gold mines that attained in their underground workings a greater depth than 100 feet:

Mikado mine, depth between 800 and 900 feet.
Sultana mine, depth between 500 and 600 feet.

View on Railway from Mine to Mill at Camp Bay.

Mikado Gold Mine, View of Works.

stamps to 40 stamps. The total number of stamps installed was 460. With the exception of a very small number these were all erected on Western Ontario gold mines.

The most important producers during the last years active work were the Sultana, Mikado, Sakoose,

Three other mines, depth between 400 and 500 feet.
One other mine, depth between 300 and 400 feet.
Ten other mines, depth between 200 and 300 feet.
Twenty to thirty other mines, depth between 100 and 200 feet.

The deepest mines have been the largest producers.

To-day, transportation facilities in that western part of the province are greatly improved, along the southern boundary by the advent in 1904 of the Port Arthur to Winnipeg branch of the Canadian Northern Railway; and in the north by the addition of the Grand Trunk Pacific. In the early days, however, and even as late as 1903, the whole area was handicapped with the greatest difficulty of access. There was but one line of railway, the Canadian Pacific, in addition to which practically the only means of travel in the summer was by the endless chain of waterways, rivers and lakes, and that mostly by canoes; although on the larger lakes there were a few small steamers. On account of the numerous portages, transportation of supplies was extremely expensive, hence practically everything, and, of course, all machinery, had to be hauled in during

The final reckoning was a long time coming—years or more. There is no particular need of mou ing now. It is well, however, to profit by the err committed. These errors may have been numer but after all none compared with, and all were m or less the result of the one unpardonable sin of or sion, that in almost every case no qualified advice sought, nor apparently wanted. I have discussed fairs with mine managers whose qualifications dou less were all right up to their limit, but whose origi occupation ranged from a one time bar-tender up t General of the British army, each having in his c trol the expenditure in mining development and pl of large sums of money. Any crack in the solid co try rock, a few short quartz stringers and sim "showings" were in numerous cases sufficient for

Sultana and Burley Gold Mines.

Regina Mine

the winter months by team over winter roads, frozen lakes and rivers.

The hunt for gold had carried the prospector to such distant outlying areas that many camps in the early days of their development could be reached in winter only by dog-team, or by the lonely snowshoe tramp with pack on back. Many a time has the writer attained the end of his journey by such means, to find there a busy little mining camp with development going eagerly forward.

Such was the general enthusiasm at that time in the gold mining region of Western Ontario. No obstacle was too great to be overcome, and no expense too heavy for the investing public to meet.

establishment of a camp and the attempt to devel mine. These are the regrettable incidents. M thousands of dollars thus wasted in useless mi might have been saved by the outlay at the very ginning of a small fraction of the subsequent exp ture in fees for technical advice, which would warranted the turning down at once of such so-c mining prospects.

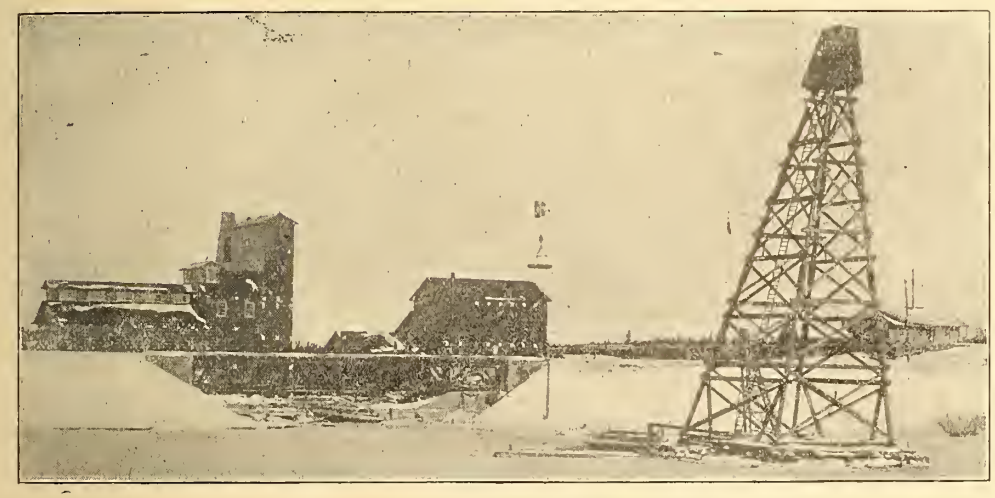
On the other hand, there were many worthy pr ties, a number of which produced pay ore in cons able quantities. Had the visibly worthless ones culled out of the way, the interest in the area w have been confined of necessity to the smaller nu of possible mines, and these would at least hav

d a longer lease of life than they did. So far as n there were no particular bonanzas, such as the nger mine in the case of Porcupine, to stimulate st. Such outstanding prizes make the heart glad, is not they alone that are able to pay dividends. an ore body of less value per ton is well worth ttention of the miner, and Western Ontario may several of these.

e worst that may be said of these more promising properties in Western Ontario is that they never fair show, either financially or, with but few exons, technically. The money of the investing or lating public was spread over an immense area ntry in prospects everywhere. It is history with ew exceptions, of which latter Cobalt may be ined, that in no mining camp or field does more than y small percentage of the properties exploited out profitably. To preserve the balance, nature ot been overlavish with the miner. Hence when t countless prospects, which either at the start er a course of preliminary development could have mpetent men been reported worthless, continued parts of this western field to give no promise of the public confidence in the whole field waned.

from their inception, twenty years ago, been carefully compiled, with the result that a complete history of the underground and surface workings of practically every property, from the prospect up, is now available as a guide to those interested. Of the actual gold content of the veins, little definite information will, however, be found. The chief reason for this is that the operators themselves did not always know. Outside of this source of information the only means of determining the same would have been by systematic sampling, and this was not one of the functions of the mine inspector.

Among the most interesting mining properties in Western Ontario, which might bear inspection, may be mentioned the Sultana, on the Lake of the Woods. This reached the depth of 470 feet at the seventh level, with many hundred feet of drifting on all the levels. One of the ore stopes was of great size, measuring (I write from memory) at its greatest cross-section about 40 feet wide, by 100 feet or more along the strike of the vein, and extending from the surface down to the fifth or sixth level. The surface plant was elaborate, including a 40-stamp mill, a roasting and chlorination plant.



Ottawa Reduction Works– Keewatin.

e deserving properties suffered with the rest.

height of activity in these western gold fields d, as mentioned above, in 1897. By 1900 the l public had lost interest (as well as their money) nly a few mines struggled on. By 1903 practievery property had ceased to operate.

cupine has come to Ontario as the saviour of the ining industry. It took a good year to instil inmind of the public and mining men alike the idea ossibly after all Ontario could produce a valuold mine.

now how rapid has been the effect upon this camp in the west end of the province. Within ar the old Mikado mine, the deepest and one of ost completely equipped, absolutely abandoned, ve, by the former operators, has been reopened ong financial interests, who have placed a ca- engineer in charge. Already an entirely new of pay ore has been found, which is now under development. Other of these better known old rties are being spoken of in mining circles and press, which can be taken as an indication of may shortly come about, the re-opening for extion at least of more of them.

reports of the Bureau of Mines of the Depart- of Lands, Forests and Mines of Ontario have

The Regina mine, on Regina Bay, Lake of the Woods, was sunk to a depth of 535 feet. At this time also extensive drifting was done. No later than 1900 the mine changed hands. More underground development was then accomplished and an entirely new reduction plant erected, including a battery of 30-gravity stamps to replace the original 20 Tremaine steam stamps. The Golden Star just north of Mine Centre in the Lower Seine River area, is another well developed property, having attained a depth of 530 feet at the seventh level, with a great deal of drifting on all the levels. The ore was treated in a 20-stamp mill connected by a mile or so of aerial cable-way with the mine.

In addition to the above, one might continue enumerating gold mine after gold mine in this western part of Ontario, each with defined and substantial veins, and all more or less elaborately equipped with the best of mining plant. Of many of these it may be safely said that the value of the veins for profitable operation has never been definitely determined.

It is not my purpose here either to state or to imply any more than this. I often enough, then and since, felt that many of the gold mining properties of Western Ontario never had a fair chance to show whether or no they were, under the proper conditions, capable of profitable operation.

An Efficient Steam Pipe Support

The accompanying sketches illustrate a design of steam pipe support which has proven very efficient about the plants of the Southern Division of the Republic Iron & Steel Company.

In figs. 1 and 2 are shown the support, which allows of a free movement of the steam pipe both in the direction of the steam line and also at right angles to that direction. The uprights are standard W. I. pipes fitted on the upper ends with standard companion flanges, and with the lower ends imbedded in a concrete foundation. Attached to the flanges is a channel iron, in the trough of which are placed five short pipe rollers at right angles to the axis of the channel. On these short rollers and with its axis at right angles to the axis of the short rollers is placed a long transverse pipe roller on which the steam pipe rests. Usually, however, a pipe saddle is attached to the pipe, and rides on the upper roller as it affords a greater bearing surface.

In figs. 3 and 4 are shown the end and side elevations of anchor towers, which are used about every twelfth support.

On one occasion in which is was desired to conserve the steam generated from the waste gases of an iron furnace, to run the plant of an adjacent dolomite (flux) quarry, an 8-inch pipe line about 1,200 feet long was used with supports spaced every 20 feet and having four anchor towers and three expansion joints. The short rollers on these supports were 6 inches long and made of ¾-inch W.I. pipe, while the long roller was of 2-inch W.I. pipe, 2 feet 4 inches long. The uprights were W.I. pipes 4 inches in diameter.

The anchor tower braces in the sketch show an item to which usually very little attention is paid namely that the brace turnbuckles to permit of convenient handling should always be placed near the ground.

AN EFFICIENT STEAM PIPE SUPPORT

Scale ¼" = 12"

On March 22 the Nelson, B.C., "Daily News" published a list of the contributions to the fund in aid of the widow and orphans of the late Fred C. Alderson, who sacrificed his own life in saving that of an Italian miner in the Bellevue coal mine, Alberta, last December. The statement, which was supplied by B. L. Thorne, secretary-treasurer of the committee having the matter in hand, showed a total of $4,795.91. To this there will shortly be added $500 from the Government of British Columbia. Probably the Government of Alberta will also contribute, if so, its amount should bring the total up to nearly $6,000

The gold output of South Africa is now one-third of the world's total. In 1887 the output was only 0.75 per cent. of that of the whole world. In 1910, $45,000,000 was paid in dividends.

PROGRESS IN MEXICAN MINING AND METALLURGICAL METHODS DURING THE CENTURY OF INDEPENDENCE

Read by A. Grothe on behalf of the Mex. Institute of Mining and Metallurgy at the meeting of the "Congreso Cientifico y Artistico del Centenario," promoted by the Mexican Academy of Jurisprudence and Legislation on Feb. 25th, 1911.

To the present generation, accustomed to look upon steam and electricity as indispensable auxiliaries to our industrial operations, means of locomotion and everyday life, the ore-yard of the Mellado and Rayas mine at Guanajuato, on an early morning of the year 1800, would have presented a strange and interesting scene.

In the dim twilight the general contour of an irregular polygon surrounded by high walls, is faintly discernible. At the corners, substantial watch towers, provided with loopholes for musketry fire, protrude above the skyline. Several massive buildings are contained within the walls, among which the splendid chapel, erected in 1730 at a cost of $54,000 by Don Vicente Manuel Sardaneta (afterwards the first Marque de Rayas) forms a strong contrast to the shingle-covered sheds in the background, where the 1,400 mules and horses forming the motive power equipment of the mine are housed. Aside is seen the gallow-frame (horca) over the main shaft of "tiro general" On each of its eight sides a set of "lechuguino" ropes are ascending to bring up water or ore and descending with tools and supplies. Just now a squad of the nightshift is coming up, clinging to the hoisting rope and dexterously jumping to the ground as the surface is reached. The men gather their rags about them as a feeble protection against the cool morning air, which they feel the more on account of the contrast with the stifling heat of the badly ventilated workings they have just left. One or the other gives a last re-adjustment to the sample of rich ore which he has concealed on his person and intends, if possible, to add to his private collection.

At the massive gateway, which forms the only exit from the yard, the portero, muffled in his sarape, is waiting to search the men before they are allowed to leave. He is a man of experience, has been through the mill himself, and is certain to detect any ordinary place of concealment on the person of those who are not friends. But a new trick may have been invented and at any rate one may succeed where others fail. Once outside the gate the booty is in no further danger and the successful robber, unrestricted by any sense of wrongdoing, (for has not God made the stones for us all?) is safe and can easily find a purchaser for his ill-gotten gains. Large sums are thus abstracted from their legitimate owners, but these themselves are not by any means free from blame in the matter, for they view these delinquencies with indulgence, and seldom take adequate steps for the punishment of the offenders. One of these gentlemen on his return from a journey to Rome, announced to his miners that he had procured for them a complete absolution for past misdoings of this kind! Thereupon the stealing went on as before, in the expectation that the owner would have to go on another journey to Rome sooner or later. Another, who acted on the principle that the people should be rigorously searched, but not molested when they got safely outside, was made the bearer of a rich sample which had been placed in his pocket by a miner who demanded it back after passing the gate, saying: perdone Ud., senor Conde, eso es mio! Such misplaced leniency bred a laxity of morals which is felt to the present day. The least of its evil consequences is the loss of a large amount of money to the rightful owner, and the far greater one that of obliterating the moral sense and honesty of a whole class of workmen, a degeneration which cannot fail to spread to their families and associates. To eradicate this evil by education will take as long a time as it has taken to grow.

The dayshift (pueble de dia) has now assembled and is mustered under the capataces near the mine entrance (boca-mina). First there are the miners, the aristocracy of the workpeople, working either in days-wages, by contract, or on "partido," in the latter case receiving by way of remuneration for their work one-half of the ore they extract. We shall presently follow them into the mine and be able to judge of their skill and methods. In the next group are the tenateros and charqueadores, the former carrying the ore and waste in sacks of ixtle fibre, hanging by a band from the forehead, and the latter the water in leather sacks suspended in the same manner. These two classes may rightly be considered the pariahs among the workers, and it is doubtful whether the mine slaves of antiquity led a more hopeless existence than these unfortunates. Probably still under the influence of last night's debauch, in which every cent of yesterday's earnings was spent; clearly not having broken their fast this morning; more than half naked, they form a pitiful spectacle and it seems impossible that they should perform the feats of strength and endurance which we shall see them capable of. They go to their work literally with nothing; having even to leave their own name behind, for each receives a new one by which, for purposes of accounting, he will be known for the day, from an alphabetically arranged list of biblical names. They are not on the regular paylist of the mine and apply for work when they choose. The capataz counts off the necessary number for each day's work from the file, the rest are sent away and perforce have to remain idle as it is now too late to apply for work at another mine. At two o'clock in the afternoon they cease work for the day and are at once paid off according to the work performed and depart to spend their earnings as soon as possible.

The pepenadores (ore sorters) have already begun their task as they too, are paid by results. They have to break the large pieces of ore with short hammers, throw out the waste and sort the ore into heaps of different classes. Not the least skilful are the women, some of whom have a wonderful eye for rich ore and consequently have to be examined with particular care by female searchers appointed for the purpose. Over every group of workers stand veladores to watch their doings. There is no sign of the slightest trust in the honesty and integrity of the people under their charge, either as concerns their abstinence from pilfering or their intention to perform an honest day's work in return for the wages received.

The capataces or foremen, after receiving their final instructions from the administrador, are now preparing to go into the mine accompanied by their morrongos, smart boys who carry a torch made out of tallow and vegetable fibre. Some of these morrongos later attain eminence as first class miners, having profited by the conversations of their chiefs.

The whole force (pueblo) has now left the patio. But who are those men, evidently waiting for coming events, with a kind of chair strapped to their backs? We are told they are the "caballitos," and on the chair the administrador or the minero mayor will presently seat himself for the purpose of making his tour of inspection through the intricate mineworkings in greater comfort than if he went on his own feet. This office, in our opinion more degrading to those who make use of it than for those who perform it for the sake of making a living, is still in existence at the time of our supposed visit, though abolished shortly afterwards.

Before descending into the mine let us cast a look at the main shaft or tiro general. It was started in 1805 by Don Jose Maria Sardaneta (second Marques de Rayas) to obtain access to the rich oreshoot of Sangre de Cristo. Its depth, when completed, will be 475 varas (398 met.) but at this time it has only been sunk 318 varas (266 met.), at which depth it is to remain for several years. The shaft is octagonal in section, measures 38 feet across, and is lined with substantial masonry from the mouth to the level at which firm rock is reached. Its cost, including accessories, has been not less than $1,700,000.

It is surrounded by eight horsewhims (malacates). The hoisting ropes lead from the overhead sheaves in a few turns round the vertical drum, to which a rotary motion is imparted by 16 horses, harnessed to four long crossbeams on which the drivers are seated. Their monotonous chant, mixed with frequent imprecations, the beat of the horses' hoofs, the cracking of whips, and the creaking of the overhead sheaves of mezquite wood, produce a strange unharmonious concert which is not easily forgotten. By keeping the horses steadily at a short gallop a hoisting velocity of 0.8 met. per second is maintained, but the horses have to be changed every four hours. Some of the malacates are used for lifting the water from the sump at the bottom of the shaft by means of a sack of about one cubic meter capacity, consisting of two raw cowhides sewn together and held open at the top by an iron ring which is suspended with leather straps from the hoisting rope. The quantity of water to be lifted is not great; about four litres per second in times of drought, to fourteen litres during the rainy season. With modern appliances, 50 h.p. would suffice to keep the mine drained; but here 576 horses, without counting the sick and invalid, are barely sufficient for this purpose.

For the hoisting of ore a single cowhide, suspended from the four corners, is used. When the load reaches the mouth of the shaft, it is pulled sideways to the firm ground and emptied. In the meantime the harnessing of the horses has been reversed and on the signal from below that the load is ready they start in the opposite direction.

We now direct our steps to the "boca-mina," a commodious entrance to a massive stone stairway, leading at an angle of 45 degrees to a large open space at a depth of about 40 feet, which has been expressly blasted out and fitted as a chapel. From here the stairway continues on somewhat less imposing dimensions, following the dip of the vein, but at times at an incline of 50 to 70 degrees. Suddenly the masonry steps come to an end and before us we have a yawning abyss, depth of which can only approximately be jud when an occasional light appears at the bottom. our left and right crooked drifts lead away, one fo ing the direct road to the loading station at the l tom of the shaft. Here a timekeeper is in attenda with the alphabetical list and a weighing beam, case of need. A weird figure, carrying a heavy l on his back, slowly emerges from the winze at our and on passing the timekeeper gives his name as A ham. The timekeeper feels the load, suggesting arrobas as its weight, and the tenatero, being satisf passes on his way. He could have the load weigh but the loss of time would not be compensated for the addition of a few pounds to his credit. The wei these men carry seems incredible, being ordina from 9 to 12 arrobas (103 to 161 kilos), but loads from 18 to 22 arrobas (206 to 247 kilos), are so times carried. A truly wonderful performance, es cially when considered in connection with the r these men have to travel 8 to 10 times a day, the vit ed air of a temperature of 20 to 35 degrees they h to breathe, and their usual mode of life. And for they receive, if all goes well and they do not slip one of the chicken ladders or get crushed by a fall rock from a shaky roof, the sum of 75 cvs! And most pathetic part of the story is that this is fa excess of what they can wisely spend.

Let us now descend to the lower workings f which our friend Abraham has just emerged. The r becomes much more difficult and without our p finding morrongo we should make but little progr After a time we turn into a low and crooked c now rising, then falling. The roof in some place so low that we are obliged to abandon the upright p tion, and again we have to scramble over debris fa from the roof. We now come to a raise accessible c by means of a chicken ladder, consisting of a si notched pole, which leads to another drift, and f there we descend into a winze at the bottom of w two men, surrounded by a misty halo, are dril holes. The drilling tool is an iron bar with a bit point of steel, and naturally has frequently to be paired. These men are "buseones," who have fo a good field and are working it for all it is wo without giving a thought to the fact that they danger the safe working of the mine. Each sq follows its own instincts, with the result that the in ior workings consist of a labryinth of intricate dr raises, and winzes, without direct connection with e other; mining, instead of being a science directing efforts to the finding of ore, and at the same tim the most rational and economical method of extr ing it, becomes simply a matter of luck. This sp characterizes the whole industry and finds even this day too many adherents, to the great detri of mining, in which, like in any other undertaking, element of mere chance should not find a place.

We leave our friends, who have no idea that by t reckless proceeding they are providing endless d culties for the future working of the mine, and make great riches forever inaccessible, with the u underground salutation "alabado sea Dios" (pra be God), and receive the pious reply, 'siempre alabado su santo nombre," (His holy name be for praised), and proceed with our investigation, now ward then backward, now down winzes and up ra to meet everywhere the same conditions: a ruined for future work by ignorance and greed.

But as we proceed upwards, out of the reach of pestilent atmosphere, and again perceive the ligh

the comforting thought comes to us that these s cannot be for ever; that a time of greater en- nment will come, and that when the yoke of op- ion under which the people have suffered for than two centuries shall have been thrown off, natural intelligence possessed by the people of co in such high degree, shall bear fruit under a and peace-loving government, and a more rational economical exploitation of the mineral resources e country will follow.

reaching the patio again, we find a scene vastly rent from that of the morning. A large cavalcade arrived and the dismounted riders are busy ex- ing the numbered ore-heaps. It is the day appoint- r the ore-sale or "rescate" and the visitors are the rs or managers of the many reduction works in valley near town, all intent upon purchasing ore heir "haciendas." Note book in hand they pro- from heap to heap, judging the weight by the and the contents by panning in a small lacquered d (jicara). They are wonderfully expert at the tion (tentadura), when dealing with ore of which have experience. The art of assaying is hardly ised as yet (any more than that of mine survey- and in consequence grievous mistakes occur oc- nally; as, for instance, when some years later ore found in abandoned workings in the upper levels alenciana, which had the look of compact iron- es and gave no indication of silver in the tenta- Nevertheless, it was found by fire assay to con- from 22 to 24 marcos of silver per "monton" (3.5 kilos per ton). Still these mistakes are the ex- on, and ordinarily the estimate of weight and nts is astonishingly correct.

hen all are ready with their calculations, the ger of the mine (administrador) takes his posi- near one of the heaps and invites bids for this per. The competing buyers approach him one by and make their bids in whispers. The proprietor e mine or his representative do the same as a pro- n against possible collusion amongst the resca- es. When after the auctioneer's solemn: No hay diga mas? no further offer is forthcoming, the of the highest bidder and the price to be paid nnounced, and the group moves on to the next on, until all are sold. In this manner thousands llars' worth of ore are sold every week. Losses nade, and great bargains secured, and it seems this gambling nature of the method makes is so ctive to those interested, that it has survived in ajuato until the end of the last century, when an Cayetano Company still sold the production their mines in this manner. And crude as the m was, perhaps no great injustice resulted to r buyer or seller. Writer had the ore offered for by those mines in 1888 carefully weighed and as- l, and found that at the end of the year the com- tion of the value on this correct basis, differed 2 per cent. with the price realized, the latter be- he higher. He thereupon published his figures e day before the rescate and sold the ore on the thereof. This put an end to the picturesque but proceeding of former times.

the conclusion of the rescate the mules which to convey the ore to the reduction works, swarm nd the arrieros proceed to load the ore in leathern s, while their masters sit down to a sumptious n, after which the tables are cleared for a friendly of cards, which is often prolonged far into the t, in the course of which many of the purchased s of ore change hands.

Not being possessed of the gambling spirit, we shall rather follow the ore to the reduction works.

At the hacienda it is weighed, without, however, a determination of the moisture being made. This and other inaccuracies make the returns as to results obtained not quite so trustworthy as might be desirable. The coarse ore (grueso) is then crushed to pea size in crude wooden stamps, or equally primitive roller-mills with stone runners, and, after being mixed with the smalls, is fed to arrastres where it is ground to impalpable slime under addition of water. The arrastre is a circular stone tub of about 9 feet diameter, half sunk below the floor and provided with a bottom of hard basalt or porphyry, the stones being placed on end. The grinding stones are large pieces of the same material suspended by chains from crossbars fixed to a vertical shaft, to which a mule imparts a rotary motion. Eighty or more arrastres are placed in row in a large shed or galera. The bottom of the arrastre is covered by a thin layer of silver or copper amalgam, to which the fine particles of metallic silver and gold contained in the ore adhere. Every morning the arrastres are emptied of the ground pulp, which goes to the "patio" for further treatment. The capacity of an arrastre is from 7 to 8 cargas (1,100 to 1,300 kilos) per day, according to the degree of softness of the ore. Every two to three months a "raspa" is made, that is, the amalgam is removed from the bottom and joints. The scrapings are thinned out with mercury, filtered, and the remaining mercury distilled off in vertical iron retorts or "capellinas." The resulting bullion, which is very rich in gold, is then melted in charcoal furnaces, cast into bars and taken to the mint, where it is assayed and parted, that is, the two metals are separated, and obtained in an almost pure state. By this process about one-half of the gold contained in the ore is recovered, the other half, remaining in the pulp, is lost, as we shall see.

The pulp is collected in flat heaps, called "tortas," each containing about 100 tons of ore, on the flagged floor of an open yard, called the "patio," from which the name of the whole process is derived. It was invented by Bartolome de Medina and first practised by him in Pachuca in 1557. It was admirably adapted to the available resources and the requirements of the country, and, crude as it may appear to the modern metallurgist, has been of incalculable benefit to the mining industry.

(To be continued.)

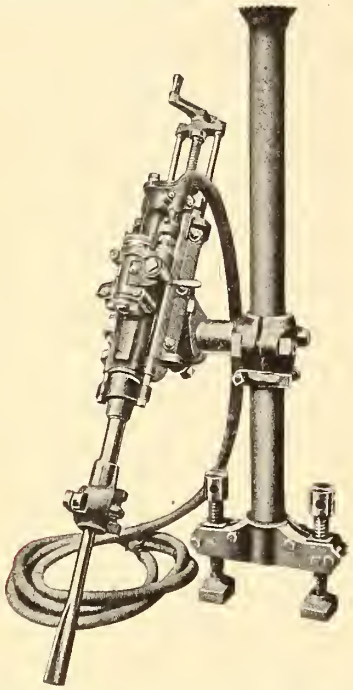
The San Salvador Spanish Iron Ore Company, Limited, an English corporation, operates ironstone quarries near Santander, Spain. The annual report of this company contains the information that in the first half of 1910 the rainfall interfered seriously with the operation of the quarries. The fall amounted to no less than 38 inches. As the ore is embedded in a very tenacious clay, it may easily be imagined that work was badly impeded. All the ore has to be concentrated. Despite adverse climate, bad labour, and low grade ore, this company has a fine dividend record.

The Crown Reserve mine, Cobalt, has paid a total of $3,006,983.80 in dividends. The record of the company by years is as follows: 1908, $353,762.80; 1909, $1,238,169.80; 1910, $1,061,288.40; 1911, $353,762.80. The grand total of disbursements is $3,006,983.80. The capital of the company is $2,000,000, divided in shares of $1 each. The stock was quoted as low as 20 cents in 1908. It ran up to $6 in 1909, and now stands about $3.20.

INDUSTRIAL SECTION

HOLMAN DRILL.

The Holman Rock Drill, which has attained success in South Africa, Australia, and Great Britain, is now being introduced in Canada.



Holman Drill Mounted on Column.

The Holman drill is manufactured by Holman Bros., of Camborne, Cornwall, who are considered to be one of the most progressive manufacturers of rock drills in the world. Established since 1839, and continually improving their product, has made the name "Holman" known most favourably wherever rock drills are used.

In bringing their drill to its present state of perfection, Holman Bros. have been materially assisted by the practical experience gained as very large users of rock drills in their numerous underground undertakings; they being miners as well as manufacturers. Their dual experience places Holman Bros. in an unique position, as compared with other makers, and is without a doubt an advantage, the value of wh cannot be overestimated by mining men the wo over.

That the Holman drill possesses real merit is sho by the many records it has established and ho Among the most important of these are:

The world's record for incline shaft sinking.

Six world's records for shaft sinking and drivi during the last two years.

Winners of the $12,000 prize in the 1910 Rand st drill competition.

Also numerous local records.

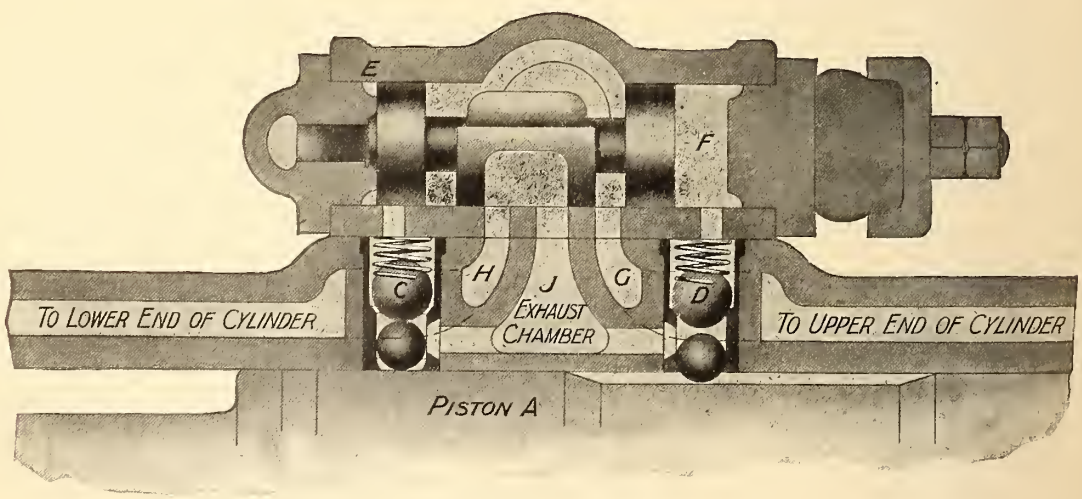
The Holman 1911 model, air valve drill, is c sidered by many mining and mechanical engineer be the best machine on the market to-day, becaus combines:

Simplicity of mechanism.
Compactness of build.
Lightness, in comparison to strength.
Quality of material and workmanship.
Economy in the consumption of air.
Economy in upkeep.
Drilling speed over long periods.

The drill has a comparatively small number of pa has large bearing and wearing surfaces, and is ea adjustable and accessible.

As will be seen from the above illustration, Holman valve is simple, durable, efficient, and nomical. There is absolutely no chance of live passing over the valve into the exhaust, and from position of the piston and valve, there can be "sticking" or "fluttering."

The Holman drill has a variable stroke, from inch upwards, depending on the size of the drill. value of this variable stroke is well understood.



Holman Air Valve.

The Holman patent chuck is without a doubt of the greatest improvements made on rock dril many years. Not only does the Holman chuck blacksmith costs, but it saves labour charges, as changing of steel is a much quicker operation with the old type chucks.

The Holman drill has a split front head, with movable half bushing, and taper gland, which is

Chuck

eid l improvement on the old style four or six-bolt hea.

l Holman drills are tested at varying pressures up o one hundred pounds, and are given a thorough tri under conditions severe as those obtaining un- del round. The drills are covered by a broad guaran- tee both as to efficiency, material, and workmanship. Jussens, Limited, are stocking these drills, with all spaes, in Montreal, Cobalt, Porcupine, and Vancou- ver and are always able to make immediate shipment of rders.

---

talogue of Eugene Dietzgen Co.—Ninth Edition —ugene Dietzgen Co., Limited, Toronto, Ont. To pu ish a strongly bound, profusely illustrated volume of nearly 600 pages is no small undertaking. The catlogue before us is one of the most complete and mo instructive that we have seen. Everything that the draughtsman and engineer need is here described an listed plainly with prices. The catalogue is so co plete, and comprises so many modern refinements, tha it is genuinely educative to study it. It can be obtined by applying to the Toronto branch.

---

he death-rate amongst mine labourers in South Af ca is 30.75 per 1,000. In 1905 the rate was 38.8.

LABOUR TROUBLES AT WESTERN COAL MINES.

Following receipt of notice from the Minister of Labour, Ottawa, that unless either the Western Coal Operators or their employees made application for the appointment of a Board of Conciliation and Investigation under the Industrial Disputes Act, 1907, the Government would proceed to appoint a Royal Commission, with power to make full investigation into all the conditions bearing upon the labour difficulties that occur periodically in the coal mining districts affected, the representatives of District 18, United Mine Workers of America, on April 13, telegraphed a preliminary request for the appointment of such Board of Conciliation and Investigation. Meanwhile it is expected the men will return to work in the mines on the understanding that whatever rates of payment to them shall eventually be agreed upon, they will take effect as from the time of resuming work.

No serious effects of the cessation of production of coal and coke have yet been felt in the copper mining and smelting districts of British Columbia, the smelteries having a sufficiently large reserve supply of coke on hand to keep their furnaces going for several weeks after regular supplies had been stopped. It is now hoped that an agreement will be reached without necessitating the shutting down of the copper mines and smelteries of Kootenay and Boundary districts. There is no certainty, though, that the findings of the Board of Conciliation will be accepted.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Dominion Coal Outputs.

The output for April is approximately 285,000 tons, this being quite a low figure. There were only 24 working days in the month. The drift ice was a great hindrance, the whole island being ice-bound. For a week together no ships were able either to leave port or to enter.

The total outputs for the first four months of the year compar during the past four years as follows:

1908	1,249,535 tons
1909	957,471 tons
1910	899,250 tons
1911	1,164,954 tons

The Coal Company is undertaking an extensive programme of improvements and additions to its plant during the ensuing summer. At Sydney a new shipping pier—to be known as International Pier No. 3—will be erected, and a Baum coal-washer, with the necessary railway extensions and sidings. In anticipation of largely increased coal traffic on the railway additional rolling-stock is being purchased, which will include two locomotives, and 100 fifty-ton pressed steel cars. Several new railway branches will require to be built to the new collieries. In the Lingan-Victoria field a large amount of new construction is projected. No. 12 Colliery is now almost complete, and is producing well over 1,000 tons daily. At No. 14 Colliery the coal is now being put over the permanent bankhead, and the large permanent hoisting engine is in use. An electrically-operated air-compressor is nearing completion and a number of percussive coal-cutters will be operated as soon as the compressors are in working order. This mine will produce up to 800 tons daily this season. At No. 15 Colliery it is intended to complete the permanent bankhead, compressors, boiler-plant and all the plant necessary to make this mine a regular producer for the season of 1912. At No. 16 Colliery the usual colliery buildings, such as wash-house, lamp-house, office, etc., will be erected, and the foundations for the bankhead put in. Contracts have been let for about 150 dwellings for the workmen and officials in this district. It is not unlikely that an electric tram-line will be constructed to connect with the Sydney & Glace Bay Railway. The population of this district is growing very rapidly, and this necessary convenience cannot be long deferred. The site of No. 17 Colliery will be cleared and the slopes driven for preliminary development.

The slopes at Birch Grove, on the narrow coal-basin situated to the rear of Morien, on what were known as the Cumberland

areas, have been developed and are producing about 1,000 tons monthly. The block of coal which it is proposed to work is quite narrow, and the slopes are being driven from crop to crop. The coal is proving to be of excellent quality and shows a good analysis for metallurgical uses. It is expected to connect the slopes with the Sydney & Louisburg Railway this summer, and to install the permanent plant. The motive-power will probably be electricity, transmitted from the central plant at No. 2 Colliery, some 5 miles away.

The Labour Situation.

The leaders of No. 26 District of the U.M.W.A. take themselves very seriously, far more so, indeed, than anyone else. It was a foregone conclusion that none of the coal operators of Nova Scotia would take cognizance of the request—or perhaps demand would be the more correct word to use—made by the Scale Committee of the U.M.W.A. for a joint meeting of the operators and U.M.W. representatives to consider a wage schedule. Nevertheless the committee attended at the place and time appointed, and afterwards gave out a statement to the newspapers that as the Scale Committee had not received the assistance of the operators the responsibility of drafting a satisfactory wage schedule had devolved upon themselves and had been undertaken. The operators will doubtless appreciate at its true value the self-sacrificing labours of this self-appointed committee. The public, if informed that the U.M.W. numbered among its adherents less than one-third of the miners of the province, the other two-thirds being at utter variance with their methods, would also appreciate the humour of the situation. It must be conceded that the U.M.W. leaders in Nova Scotia are thoroughly impressed, or obsessed, by a sense of their own importance. The Scale Committee were very insistent, both in their letter to the operators and in the statement to the newspapers on their desire to promote harmonious relations, peace, and amity all around. It is therefore significant that the submissal of this schedule to a United Mine Worker meeting at Glace Bay was attended by an unfortunate shooting affray in which two men lost their lives. It is rather singular that a propaganda which claims to have for its end the establishment of peace and harmony should have been accompanied by riots, shooting affrays, murder, dynamiting, and other little pleasantries. The leaders of the United Mine Workers of America in Nova Scotia preach with whole-hearted enthusiasm the principles of international Socialism. These principles viewed academically and in the abstract, may be held by the quietest of men, but translated into action by unlearned and untravelled miners, who follow the lead of agitators irresponsible and destructive to the extreme, even abstract principles become dangerous. But when these doctrines are preached by citizens of the United States, who are here to-day and gone to-morrow, who regard with undisguised contempt the laws of Canada and teach that all forms of outward authority are the outcome of capitalistic oppression and bureaucratic greed, the menace is no longer local, but national.

There are not lacking signs of dissatisfaction among the local members of the U.M.W. with the dominance of the Socialists, and it may well be that the doctrine of the social revolution will prove the final undoing of the U.M.W. in this province.

Since the appointment of the Police Commissioner at Springhill, conditions have steadily improved. It is now possible for the men who are at work to visit the town and to move about without molestation. The strikers are returning to work in twos and threes, and it is the general opinion that the strike cannot last very much longer.

Fatal Accidents and Work.

The "Colliery Guardian" recently had a short paragraph stating that an English colliery company and its workmen had entered into an arrangement whereby in the event of a fatal accident in the mine the work should not cease as had hitherto been the custom. The colliery company undertook to contribute £25 and the men devoted a portion of their earnings to the relief of the dependents of the deceased workman, wh they could easily afford seeing that their earnings were not duced by going home after a fatal accident. This seems a v practical solution to a difficulty which is felt at every collie benefitting, as it does, the colliery company, their workm and the relatives of those who are overtaken by death in mine, and should commend itself to employers and workmen Nova Scotia.

ONTARIO.

Cobalt and Other Silver Areas.

A disagreement as to site having led to the abandonm of the establishment of a customs plant at Kerr Lake, Crown Reserve Mining Company has signed a contract with Nova Scotia Mining Company to have all its low grade treated at its mill. The Nova Scotia mill is a distance 5,000 feet from the Crown Reserve, and the distance will bridged by the construction of an aerial tramway to be bu by the Nova Scotia. Under the terms of the agreement Nova Scotia is required to treat the ore and return the bull to the Crown Reserve for shipment. The contract calls a hundred tons of ore per day for five years. The Crown serve has on the dump alone 35,000 tons that will run betw 15 and 20 ounces to the ton.

With the improvement of power conditions the product of the camp has reached a normal level again. The Brit Canadian has now all the water that it can possibly requ and is giving full pressure to all its customers at Cobalt, K Lake, and South Lorrain, and there is very little probabil that there will be any serious breakdown this season. Cobalt Hydraulic was not so fortunate. No sooner had t company a sufficient head of water, when there was anot accident at the intake pipe and the power had to be shut for a time. It has now been turned on and there should be further intorruption of service. That the interruption of pov has been a source of great loss and inconvenience to the wh of the Cobalt camp needs no demonstration.

Many silver prospects allowed to lie idle while the air v off are now going to be worked again. This is particularly case round Peterson Lake, where most of the leases will worked this summer. There will again this summer be a termined attempt to find ore on some of the silver prospe

The Nipissing is prospecting with but a small gang this s mer, the management having decided to carry out the grea part of the surface work with a turbine pump to wash off overburden. The gang of prospectors will thoroughly tre that portion of the conglomerate area adjoining the Sav mine on the east side of Cart Lake, where so far no systema surface work has been carried out. The turbine pump will stationed on Cobalt Lake and will operate on Nipissing Hill

At a depth of 450 feet the Carson vein of the Crown Rese shows two inches of 1,000-ounce ore. The greater part of output is still from the 100-foot level, where exploration showing extraordinary enrichment in a very small area.

The Crown Reserve is shipping but a very small proport of low grade ore and the management states that for the p three months the ore despatched will run 5,000 ounces.

Development work at the Lawson has now been resumed, being available as required. A raise has now been put up 60 feet from the 200-foot level of No. 8, and while the ore by no means as spectacular as in the bottom, it still sh in the roof of the stope. When the main shaft is connec with the 200-foot level of No. 8, No. 8 shaft will be sunk to 300-foot level and the vein cross-cut. From No. 8 a long cr cut is being run to catch No. 9 vein at 125 feet. This l near the Foster line has shown up some unexpectedly g ore during the past quarter and has contributed handsom to the monthly output of the mine.

In prospecting its claim near North Cobalt the Temiska ing Mining Company has opened up a narrow calcite vein ab an inch wide showing flakes of native silver. This, and fact that some nice ore has been taken out of the 100-f

of the Green Meehan, will ensure active development of any prospects in the Township of Bucke between the ce of North Cobalt and Lake Temiskaming.

At he beginning of next month Mr. Chas. A. O'Connell will ate upon his duties as manager of the Trethewey Cobalt in place of Mr. George MacNaughton, who has resigned to look after his Porcupine and Nova Scotia interests. During the past wo months two new finds have been made on the Tre-hew', one at the No. 4 shaft near the T. & H. B. line, and the the at the 60-foot level of the old No. 1 shaft.

Th Silver Leaf shaft is now being pumped out preparatory o pu ing down the shaft to a depth of 450 feet. It is under lease o the Crown Reserve and the work is undertaken by th t ompany.

Th e is little doubt expressed that the Cobalt Central will ome nder the hammer when it is offered for sale on May 18.

Th e are at the present time five men working on the entr l property, one to look after the pump and the other four caretaker of the building and to keep steam up in the boiler At the bottom level of the mine the vein in one place sh w two inches of rich ore in the floor but otherwise the pro y seems to have been pretty well stoped out.

Ow g to power conditions last month the Nipissing was for two eeks compelled to cease underground work entirely and, speak g generally, its operations during April consisted mainly in pu ing ore from old stopes.

Porcupine and Other Gold Areas.

Th e passage over the Porcupine trail has always been poss le, this spring it has been arduous and no one who could escap it has made it. Consequently there has been comparatively little intercourse between the Porcupine camp and the outsi world; nor will there be until the railroad gets in, about the b ginning of June.

Th e has been much building activity at South Porcupine. The ovincial authorities are forcing the burning up and disp l f all rubbish, but the water question still remains unsolved The wells that are being used should be safeguarded from ontamination by a collar of clay or concrete. At South Porcupine there is some talk of getting water from Porcupine River

Wi increased interest in the Porcupine camp all over the world sales of properties for big sums are reported. The claims of th Watson syndicate have been sold to Mr. Frank Armstrong of New York, for $25,000; the Brydge claims in Deloro have een taken over by an English syndicate and a preliminary payment made on the total purchase price of $200,000. e Martin properties have been sold to New York capitalist and many other purchases have been made. English syndi ites, while unwilling to make substantial first payments, are eager to take over claims at big prices if long options are grant .

Bef re the ice went out and left the Cripple Creek district isolat , some excellent samples were brought down from this camp 0 miles to the west of Porcupine. Two hundred men remaine d in there doing their assessment work. All the veins occur n intrusions in the granite, and while there is little visibl gold, the assays run surprisingly high from many of the best aims. An engineer of Augustus Heinze has been in the camp nd has taken up some properties, and a Scotch company known as the Aberdeen syndicate, has bought some claims and is now working them. The Great Northern and the Josey, Wood syndicate, sent in three months' provisions to their gangs f men before the ice went out.

Sev al mining men with prospectors in the field are taking stere in the finds reported in the Matachewan district half way b tween Gowganda and Porcupine. Nothing can be known r so e weeks yet, until men can be sent up to make a thorough xamination.

The Great Eastern Mining Company, with properties in De- installing prospecting plant and will at once sink a t o a hundred feet.

Underground work has been resumed at the Dome, where the main shaft is now being sunk to the 500-foot level. Good progress is being made with the new power plant and the big mill.

Interest in gold at Porcupine has wakened speculative interest in the yellow metal in other centres. A considerable number of men are waiting with their outfits ready for the first news that they can get into the Keekeek country in Northern Quebec. In the meantime many are going into the Swastika country, where the inevitable townsite is being laid out for the first flight of stakers and settlers. Mr. Frank Armstrong and other big interests have bought claims in here and a considerable amount of work is being undertaken in the neighbourhood of the Swastika mine, from the lower levels of which it is reported some very rich ore is being taken.

From the Jupiter properties near Pearl Lake comes a report that an excellent discovery has been made. All of the specimens brought into camp were chipped, so it was stated, from the surface of the main vein. Captain Anchor, of the Dome Extension, is sampling the property, and when his examination is concluded the owners will know better what they have got. Mr. A. W. McDougall, of Montreal, has acquired control of this company.

In opening up a wood road on a part of the property hitherto unexplored, the Porcupine Imperial exposed a wide lead of quartz in which some free gold was discovered.

The burning of the sawmill at the Cobalt Power Company's plant at the Mattagami River will not set back the opening of the service more than two weeks. It is confidently expected that the Hollinger and adjacent properties will be given the opportunity of getting electric power by the middle of June or before the railroad reaches the gold camp.

BRITISH COLUMBIA.

East Kootenay—The "Prospector," published at Cranbrook, recently printed the following comment on district mineral resources: "We are proud of the progress made in the development of the Cranbrook district, but do we recognize that we have not exploited ten per cent. of the area of the district? Think of the extent of its mineral wealth in the shape of gold, silver, copper, and lead, which has been proved to exist in the few square miles which have been developed, and enquire what there may be in the thousands of miles which have not had a dollar expenditure. . . Think of the magnificent water-powers on fifty rivers and streams and only three—Mark Creek, Bull River, and Wasa Creek—in process of development.

"We see what the development of a small fraction of the coal areas has done for Southeast Kootenay. We know what the operations of the North Star, St. Eugene, and Sullivan have done for the mining interests of the Cranbrook district The actual development of these big silver-lead mines to a shipping stage entitles us to the first position among the mining districts of British Columbia. The whole Dominion can see the result of the opening of the coal areas in the Crow's Nest Pass by the building of the Crow's Nest Railway, but can anyone realize the extent of the prosperity to Cranbrook and the whole of Southeast Kootenay when the Kootenay Central Railway shall be completed and in operation? What shall we do to induce capital to take hold of our yet undeveloped water powers, timber, and mining resources? This is a question which affects us all, for we have the most valuable and largest undeveloped resources of any district in British Columbia."

The Prospector's information may be supplemented by the statement that the aggregate production of the St. Eugene mine alone to date is about 1,000,000 tons of ore, containing approximately 5,300,000 ounces of silver and 225,000,000 lbs. of lead, of a combined value of about $11,000,000. The production of coal from Crow's Nest district coal mines in British Columbia has reached an aggregate of approximately 9,000,000 short tons gross, part of which has been made into

coke, of which latter, between 2,200,000 and 2,300,000 tons has been made. The total value of this fuel—both coal and coke—may be placed at not less than $30,000,000.

Kaslo.—There now appears to be promise of the Kaslo & Slocan Railway from Kaslo to Sandon being again placed in running order. The Nelson Daily News has published an account of a public meeting held in Kaslo on April 21, under the auspices of the local board of trade, at which there was announced a definite plan for repairing and again operating this railway. It is stated that the Great Northern Railway, owning the line, offered the line to citizens of Kaslo for $25,000 if that amount should be forthcoming by April 30. Negotiations were opened with the Provincial Government with the object of obtaining from it financial assistance requisite to allow of the railway being repaired and bridges rebuilt, providing new rolling stock, and for making other necessary improvements. It has been announced that the Government has guaranteed a loan of $200,000 for three years without interest, and this amount, it is estimated, will be sufficient for the purposes indicated.

Slocan.—The Van-Roi Mining Company's new concentrating mill had, by the middle of April, produced about 350 tons of silver-lead and silver-zinc concentrates. The first starting of this mill took place on March 15, after many delays caused by non-delivery of some of the machinery and plant by those who had the contract to supply it. The new equipment, having been adjusted to suit Van-Roi ore, is working effectively, and a long run is confidently expected, there being much ore blocked out in the mine ready for stoping. The management of the Standard mine, which is situated on the opposite side of Four-mile Creek to the Van-Roi, is proceeding with preliminary work in connection with the erection of a concentrating mill, provision of water supply for the mill, and construction of an aerial tramway between mine and mill. Meanwhile good progress is being made with the further development of the big orebodies opened in the mine. The season's work on the Slocan Star group, near Sandon, has been commenced. It is reported the Colonial, a Slocan mine over which there has been much litigation, is to be worked again this year.

Nelson.—The Consolidated Mining and Smelting Company is repairing and remodelling the concentrating mill at its Molly Gibson mine, above Kokanee Creek. Tests of ore from this mine have been made at the company's testing plant established last year at its St. Eugene mine, East Kootenay, with the result that changes in the Molly Gibson mill are being made for the purpose of ensuring the saving of a larger percentage of silver and lead from the second-class ore that has to be concentrated before shipment to the smeltery. More work is to be done on Eagle Creek this season; the Shoestring group has been bonded to Spokane men, who state they intend deepening the two 30-foot prospect shafts and afterwards to drift. Some rich gold ore has been taken out of this prospect, which is situated in the vicinity of the Granite-Poorman gold mines, the latter having been productive for years. The Athabasca is reported to be developing profitably, and yielding gold to an extent that is encouraging those operating it to plan for production on a larger scale. There is a 10-stamp mill and cyanide plant on the property, which in past years was one of the important producers of Nelson district.

Sheep Creek.—Vancouver men have purchased nearly 142,000 shares of treasury stock of the Nugget Gold Mining Company at $1 per share, this sale bringing the total of issued capital up to $500,000. In connection with this transaction, it is stated that the proceeds of sale of these shares are to be used in further developing the Nugget mine, and in the erection and equipment of a 20-stamp mill and providing other plant and machinery requisite for the economical mining and milling of the gold ore, of which there has already been proved to be ample to warrant putting in the mill and considerably extending the development work in the mine. The registration of the Mother Lode Sheep Creek Mining Company has been gazetted; its authorized capital is $1,250,000, and its head office in city of Portland, Maine, U.S.A. Mr. E. C. Wragge, of Ne is attorney for the company in British Columbia. Report developments at some of the other Sheep Creek properties, t that have not yet commenced production, are, in severa stances, favourable, and the outlook for a busy season in part of Nelson mining division is considered promising.

Rossland.—A news despatch from Rossland states that Consolidated Mining & Smelting Company of Canada, Lim intends to increase the quantity of ore sent from its Ce Star group of mines to its smelting works at Trail to 90 950 tons a day. The Le Roi mine is still shipping a com tively small quantity of ore to Trail. It is stated on authority that it is making a profit on its limited operat and that a few more men will be employed from now on. March report of the Le Roi No. 2 Limited, has been pri The information given includes the following: "Josie mi Shipped 2,240 tons of ore and 147 tons of concentrates. ceipts from the smeltery were $34,289, being payment 2,133 tons of ore and $4,573 for 147 tons of concentrates; i $38,862. Estimated costs for corresponding period were: velopment work, $8,000; ore production, $11,000; milling, 600; total costs, $20,600." Development of the Cliff min the Granby Company, under a working bond and option of chase, is being continued, but it is not yet sufficiently adva for much to be known of the ore-producing capabilities o mine.

Boundary.—While the Granby Company still has a cons able quantity of coke in reserve at its smelter at Grand F the work of raising it to the furnace charging bins, into v under ordinary conditions the coke is dumped direct fron cars bringing it from the ovens) is too great to admit c eight furnaces being operated, so two have been blown out is stated that there is sufficient coke on hand to meet th quirements of six blast furnaces until about the middle of but if operations shall not be resumed at the collieries a or two before then, it will not be practicable to keep smeltery running. The British Columbia Copper Compa supplementing its coke supply on hand by shipments of sylvania coke, notwithstanding the higher cost of this from so distant a source of supply. This company is now ing its Lone Star mine, situated immediately across the national Boundary line, and distant nine or ten miles fro smeltery, to which the ore is conveyed, first by a long tramway to near Boundary Falls, and thence to Greenwoo railway. A vein of ore of good grade has been cut in th tunnel the Greenwood-Phoenix Tramway Company is dr from Boundary Creek into the mountain towards Phc Where cross cut in the tunnel it is 818 feet from the surfac

Portland Canal.—Recent information received at the land Canal Mining Company's office is to the effect that i 2 adit another shoot of ore of good grade has been en and the working for 40 feet is in it with ore still in the of the drift. The ore varies in width from two to six feet. 3 adit, which had been in concentrating ore, at last a seemed to be entering the downward extension of the ore just mentioned as having been opened in No. 2.

At the annual general meeting of shareholders in the St Mining & Development Company, held in Victoria rece the directors reported as follows: "The tunneling done d the year on the four ledges amounts to about 1,000 feet. No. 4 ledge, where the most work has been done, an ore of great promise was encountered. Considerable work has done and a winze sunk to a depth of 50 feet in this ore. ledge widened with depth. Careful assays taken all the down, give an average value of $20 per ton in gold, s and lead. This is highly satisfactory, but, owing to the ence of water, we decided to postpone work on the winz the present and continue drifting in the face of the tunn this ledge, which is one of the best on our property. A time of writing we are advised by the foreman at the

work on this drift continues to expose good ore. . . st feasible plan for working the property as a mine by a tunnel from the Bear River side. This will obe necessity of constructing an aerial tramway, and will proximately 700 feet vertical depth below the present s, beside permanently draining the mine. The mouth tunnel will be only a short distance from the railway, ill be in operation before the end of next June. At a stimate, the tunnel will be 1,000 feet in length and, spur from the railway to its portal, it will facilitate g the ore at lowest possible cost.'' It is estimated t will cost about $20,000.

Hidden Creek copper mine, on Observatory Inlet, an arm land Canal, which mine is under option of purchase to aby M. S. & P. Company, Limited, is reported to be well. According to a printed statement attributed to y P. Graves, general manager of the company, ''the property has developed tonnage much more rapidly than we expected or hoped for, and has revealed ore in the deeper levels of considerably higher grade than was known to exist at the time we bonded it. Everything indicates that it is the best property we are now developing, and it is going to make a most important producer.''

It has been announced that the Glacier Creek Mining Company has made arrangements with Mr. W. J. Elmendorf (with the approval of the Portland Canal Mining Company, of which he is general manager) to direct development work on its claims throughout the ensuing summer. As its property is in the same part of Portland Canal district as that of the Portland Canal Mining Company, the additional work this arrangement will entail is not likely to interfere with Mr. Elmendorf's continued close supervision of operations at the latter company's mine and concentrating mill.

GENERAL MINING NEWS.

NOVA SCOTIA.

ness, May 1—W. D. Barclay, general manager for Mac- & Mann in Eastern Canada, visited Inverness some days McGillivray, the superintendent of Mackenzie & Mann's rests in Cape Breton, accompanied the general manager tour of inspection. So far as can be learned, it apat Superintendent McGillivray's jurisdiction will soon the famous ''Chimney Corner'' coal property. The from a reliable source is that Mackenzie & Mann intend lop this rich and extensive coal bed.

hreatened difficulty between the U.M.W. and their emhere will not result in a strike. Both parties underat in future arbitration will be first invoked. Manager McLeod has the confidence of the men.

extension of the railway line to St. Rose is an early ity. It is contingent upon the projected development St. Rose coal deposits.

ghill Mines, April 26.—Some sixteen English miners eir families arrived in town on Monday, having been t out under contract with the Dominion Coal Company. ars that they understood they were to work in Glace nd when they arrived here and found a strike on they committee to interview the officers of the local union U.M.W. They did not show up for work on Tuesday, day nearly all began work, the remainder leaving for al, where they will probably go to the West for emnt.

evening some nineteen Spaniards arrived to work in es here. They were also brought out by the Dominion ompany and are the first of their nationality to arrive n. It is claimed that they are good miners and present ype of manhood.

ght twelve more English miners arrived and will add to t of employees of the colliery. They are experienced and will add materially to the working of the mines.

fax.—Anticipating the construction of the new Canavy, the Nova Scotia Steel & Coal Company is about all machinery and adopt a scale of manufacturing far in e of anything yet attempted in Canada, which will enhe company to manufacture all classes and kinds of st steel forgings. A new forge house, equipped with e hydraulic forging presses, is to be built at New Glas- This plant will be able to handle work of a much larger ion than ever before attempted in Canada, and in size, ent and capacity will rival the best similar establishin Great Britain or Germany.

ONTARIO.

nto.—Silver Queen shareholders at their annual meeting voted to increase the capital from $1,500,000 to $2,000,000. The company's assets were shown to be $51,074, and their total liabilities $3,593.

The statement showed a nominal loss on operations to date of $27,518.74. Messrs. E. P. Smith, J. H. Stephens, H. Yeomans, Thomas Shortiss and N. D. MacLean, all of Toronto, were appointed directors for the ensuing year. The first two named were on last year's board.

Cobalt, May 5.—The power situation is gradually improving. Yesterday two carloads of machinery arrived at Gillies depot for the Cobalt hydraulic plant. It will be floated down with expedition. For the present, temporary head pieces over the intake pipes are working and since Sunday morning a pressure sufficient to work drills has been maintained. It is hoped to get the permanent machinery in next week. With two power plants furnishing air again many silver prospects are getting ready to start development again. On Peterson Lake, Cross Lake and Giroux Lake, companies that were obliged to shut down when the air went off are preparing to resume operations. The Cobalt Gem, a Philadelphia flotation, will diamond drill from the bottom of their shaft when air is available.

Cobalt, May 3.—A contract has just been let whereby the Nova Scotia Mining Company agrees to treat at its mill 100 tons per day for five years, of ore from the Crown Reserve mine.

South Porcupine, Ont., May 6.—Favourable weather has done much in clearing the trail into camp. The usual spring weather is a rainy season following the long winter, causing everything to be covered with slush and mud. This year bright sunshine, almost summer weather, followed the breaking away of winter, and the snow went off with a rush.

BRITISH COLUMBIA.

Phoenix, B.C., May 5.—Negotiations are now under way for the bonding of the McKinley group of claims in Franklin camp to the British Columbia Copper Company.

The property is owned by the McKinley Mines Company, Limited, and a meeting of shareholders will require to be held before the deal is put through.

The ultimate consideration for the McKinley group is $100,000, with an initial payment of $1,000 on the signing of the bond. The option will extend over a period of 12 months, during which time the company will carry on vigorous development work and prove up on the property. Although provision is made for an extension in the time of the bond the company intends to have it sufficiently developed within the year to warrant full payment.

Nelson.—The various contracts in connection with the mill of the Mother Lode mine on Sheep Creek have been let, the machinery will shortly commence to arrive and work will start

immediately. These facts were admitted last night, May 2nd, by William Watson, general manager and consulting engineer of the Mother Lode Sheep Creek Mining Company, who has just returned from New York.

YUKON.

Dawson, Y.T., May 3.—The spring clean-up in the Klondike district has begun. Water is running everywhere and hy[dr]lic plants are getting into action. All the large dredges [are] started and individual miners are washing out their [sl]dumps. It is believed that the gold output this year wil[l be] the largest in years, early estimates placing the yield in ex[cess] of $5,000,000.

COMPANY NOTES

Bell's Asbestos.

The directors of Bell's United Asbestos Company recommend the payment of a balance dividend of 1s. 6d. per share, making 12½ per cent. for the year. The amount to be carried forward is £16,122.

Northern Ontario Exploration Company.

The report of the statutory meeting of shareholders of the Northern Ontario Exploration Company, held in London on April 24th, has just been received. The Earl of Erroll presided, and in his address gave some interesting information. The company was formed in January, 1911, with a capital of £400,000. Of this, 100,000 shares, or £100,000, have been issued and freely called up. The company was formed to acquire properties and mining claims, and to carry on generally the business of an exploration and finance company, primarily in the Porcupine district of Northern Ontario.

Mr. C. A. Moreing and Mr. David Richards came to Canada and entered into negotiations with Messrs. Timmins, who owned a group of fifty mining claims, which claims are believed to occupy some of the most favourable positions on the Porcupine field. As a result of these negotiations a one-half share in the whole of the fifty claims was acquired by the company.

There is a group of four claims at the end of Gillies L[ake] which is in a direct continuation of the Hollinger line of r[eef] and on the south claim a big vein has been located sho[wing] gold. The claims known as the Miller claims are on the di[rect] line of veins of the Rea Mines, Limited. Veins showing [gold] have been discovered on this property.

At the extreme north there is a group of five claims, on [one] of which a large vein showing gold has been discovered. T[hese] are three claims situated on the line of reef of the D[ome] extension. There is also a block of fourteen claims situ[ated] at what is known as the "Reserve." It is stated several large veins have been located on this group. All the claims have been selected because they have showings of [gold] and veins of some sort or other on them. These fifty cl[aims] thus jointly owned by Messrs. Timmins and this company [have] recently been acquired by the Ontario Porcupine Goldf[ields] Development Company, Limited. This company has [been] formed with a capital of £600,000, in 600,000 shares of [£1] each. Mr. Moreing and Mr. Richards, while in Canada, [were] also successful in acquiring, on behalf of the company, 50[,000] shares in the Hollinger Gold Mines, Limited, owning the [well] known group of Hollinger claims.

STATISTICS AND RETURNS

DOMINION STEEL IN APRIL.

April was a good month at the Dominion Steel Works, although no records were broken. The output follows:

	Tons.
Coke	36,142
Pig	21,580
Ingots	24,875
Rails	11,570
Rods	8,390

The shipments totalled only 17,825 tons, but over 7,000 tons of rails are stocked awaiting the arrival of a steamer.

In the by-product department, there was a record output of sulphate ammonia, 380 tons being turned out.

The coal output for the four months ending the last of April totalled 1,165,000 tons, being an increase of 250,000 tons over the same period last year.

DOMINION AND N. S. COAL COMPANIES.

For the first three months the Dominion Coal Company's shipments showed a substantial increase, as follows:

Three months 1911	602,373
Three months 1910	510,082
Increase three months 1911	92,291

The coal shipments of the Nova Scotia Steel & Coal Company for the same period were under last year. The figures follow:

Three months 1911	83,455
Three months 1910	103,565
Decrease three months 1911	20,110

BULLION SHIPMENT.

The Crown Reserve sent out 23,128 ounces of silver in bars to London, England, on Tuesday, May 2nd. The shipment was valued at nearly $12,000. To date, this year, nearly a million of bullion has left the camp, the bulk of it going across the water.

COBALT ORE SHIPMENTS.

The shipments for the week ended April 28th were:

La Rose, 3 high, 1 low	272
McKinley-Darragh, 3 high	186
O'Brien, 1 high	64
Chambers-Ferland, 1 low	64
Cobalt Lake, 2 low	124
Trethewey, 1 high	63
Nipissing, 1 low	61
Buffalo, 1 high	61
Provincial, 1 high	40
Total	938

Pounds.

GRANBY.

During the first quarter of the current year, Granby produced 5,380,159 pounds of copper, 107,311 ounces of silver and 13,551 ounces of gold. There was produced during March 988,341 pounds of copper—the largest output for many mo[nths] —40,400 ounces of silver, and 4,912 ounces of gold.

SILVER IN APRIL.

Average prices of bar silver in London during April [were] one-eighth of a penny better than during March. There

little change in average monthly quotations this year. ighest was 24⅞ in January, followed by 23¾d. in Febru- to 24 5/16 in March and a slight recovery to 24 7/16d. for A year ago the April average was 24½d., against in 1909, 25⅛d. in 1908, and 30¼d. in 1907.

BRITISH COLUMBIA ORE SHIPMENTS.

following are the returns of the ore production and movement for the past week, ended April 28, and for the year to date:

Prompt and Satisfactory Returns

The North American Life is continually receiving from policyholders unsolicited letters like the following, expressive of their appreciation of the treatment accorded them and results attained:

The holder of Policy No 8192 wrote:—
"I appreciate the promptness with which you have remitted the amount due me. I may say that I have nothing but praise for your company for the very satisfactory way in which I have always been treated. Our business relations have been very pleasant and I wish the North American Life the future success it so well merits."

The holder of Policy No. 9205 said:—
"I cannot close matters with the company without expressing my great appreciation of its methods and the very fine manner in which I have been treated by its representatives. In the 20 years of dealing I can recall no single instance in which I have received anything but courtesy and business promptness. I hope to renew relations with the North American soon in respect to my children's insurance."

The Financial Position of the Company is Unexcelled.

Nissen Stamp Mill

The Nissen Stamp Mill

STAMP. The Nissen Stamp drops with great crushing effect upo a feed comparatively free of the fines caused by preceding impacts This causes an actual splash which radiates from the centre of the die carrying the pulp to a circular screen, every aperture in which present a full opening for the pulp which has already reached size to pas through. As the stamp ascends preparatory for the succeeding blow, partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated type "B" Nissen Mortar.

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Toronto, Canada.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wit a large part of Canada, with many local areas and special subject

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definately the precise area cc cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for whi it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mini Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of 1 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and econom geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature r ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postag

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

Smelting and Refining Electrically

THE REID SYSTEM

Fundamentally different from all other methods, electric or otherwise.

Fusion takes place within 10 seconds after current is applied, without previous preparation of furnace.

Smelting can be started and stopped at will, instantly, without reference to condition of charge.

"Hangs" and "freezes" cannot occur.

No fluxes of any kind are used.

No milling, concentrating or sorting is necessary, as the Reid Electric Smelter takes "run of the mine."

Recovery is practically complete, repeated tests demonstrating that less than 1-10 of 1% metallic remains in the slag.

All By-Products are saved. No fumes, gases or vapors escape into the atmosphere.

Refractories and deleterants have no destroying effects. The charge never comes in contact with the walls of the furnace; no furnace linings are used.

Smelting and refining are continuous and complete at one operation. Returns can be had immediately.

Reid Smelters are built on the unit plan, can be operated as a whole or in part, with different units of different capacities, or with as many different units as there are different grades of ore to be treated. Construction is such that complete plants can be packed over the most difficult trails to the most inaccessible mountainous regions.

Heat attained in the furnace is over 6000° Fh. as against 2200° to 3300° Fh. in a blast furnace.

The Reid System is automatic in operation and control, self-regulating and self-adjustable to the pre-determined requirements of the particular ore under treatment.

Cost of coal, coke, fluxes, etc., and freight charges thereon, is absolutely eliminated.

Construction cost is 25% to 75% of that of a blast furnace of similar capacity, depending upon the character of the ores to be treated. Operating cost is fully 50% less.

We have yet to find the ore the Reid System will not handle completely and successfully.

TO MINE OWNERS

Our purpose is to give every mine owner in the world

the opportunity to have his own smelting and refining plant right at his mine, and to get for himself all the metal values and by-products his ores may contain. Any responsible mine owner can secure from us a license to operate under the Reid System upon a royalty basis.

Public demonstration every Wednesday at 11 A. M. at 352 Mulberry Street, Newark, N. J.

Complete illustrated description mailed upon request.

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners, Chilled Wheels and Castings of all descriptions.

THE

SUDBURY CONSTRUCTION & MACHINERY CO.

LIMITED

SUDBURY :: ONTARIO

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unsurveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minimum being 40 acres in unsurveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries.
Quebec.

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOT

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Si $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Mine or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,57 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral lan been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

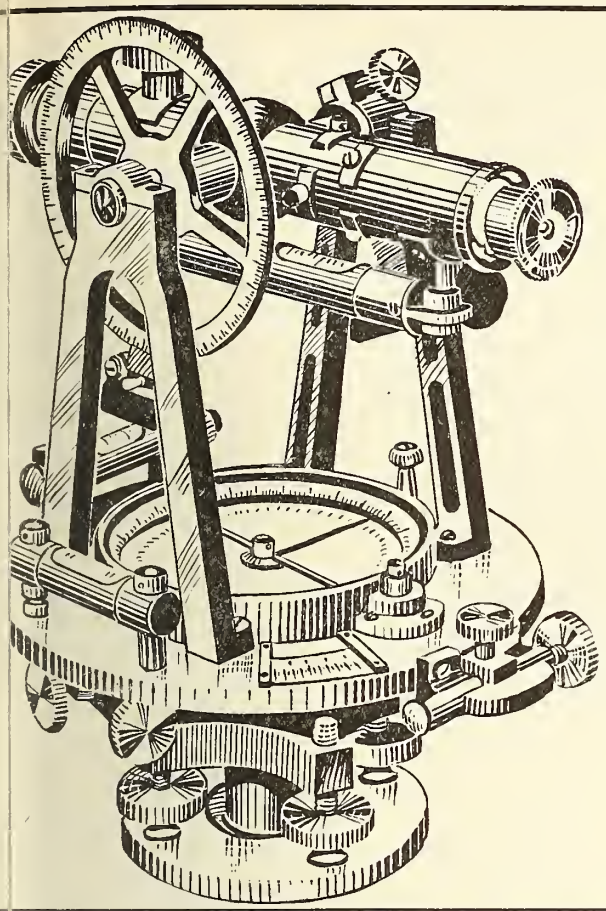
The Mining Laws of this Province are more liberal and the fees lower than any other Province i Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guarantee Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES



High-Grade Transits

Keuffel and Esser Transit No. 5165

This transit is designed to meet the requirements of the mining engineer. It is a sturdy instrument and will stand the roughest kind of work. It weighs 10¼ lbs., telescope 9 ins., object glass 1 in., vertical limb 4 ins., horizontal limb 5½ ins. All graduations on solid silver. Four leveling screws of solid German silver.

Instrument complete with tripod - **$195.50**

Instruments of this make are recognized all over America to be of the highest standard of manufacture. Every instrument carries with it our unqualified guarantee.

Another value that will interest surveyors is our Railroad Dumpy Level at **$80.**

And you'll find here a splendid selection of engineers' chains, steel and cloth tapes, tracing linen, etc., of the most dependable kinds.

Optical Section, Second Floor.

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

---

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

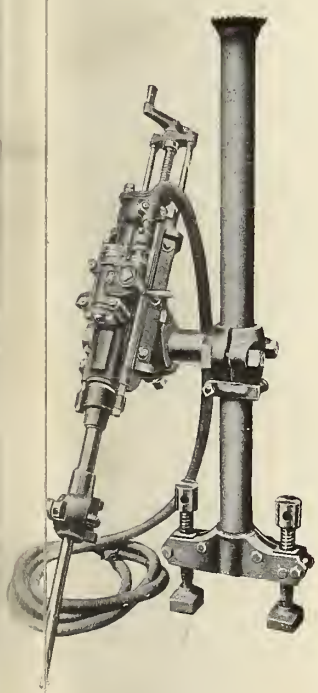
2 TORONTO No.

READ THIS LETTER
FROM A SATISFIED USER OF



THE HOLMAN DRILL

We can convince you also.

We have records showing increased footage at lower cost for air than any other drill of equal size.

Cobalt Lake Mining Company,
Cobalt, Ont., Apr. 26th, 1911.

Mussens, Limited,
Cobalt, Ontario.

Dear Sirs:—

Replying to your favor asking me the results I had obtained from the use of your Holman Drill.

I beg to state that I greatly prefer your drill to any on the market. I have used practically every drill made, and find in your drill a less consumption of air and much greater capacity. I have found by repeated trials that your drill works better, as compared with others, running under high pressure.

The proportionate increased capacity of your drill decreases with the pressure. Running under about 65 lbs., it is on a par with other Standard Drills, but the moment the pressure is increased above this point we obtain better results with your drills than others.

I have used your drills for the past year, and find that, if anything, your repair bill is smaller than any other machine. One machine which I have had in use for a year is in just as good a condition to-day as when I got it.

Yours very truly,
(Signed) M. B. R. GORDON,
Manager.

Renold Patent Silent Chains

What Users Think

MONTREAL, Feb. 8, 1909.

Messrs. Jones & Glassco, Montreal.

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your enquiry of Jan. 30th, I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.

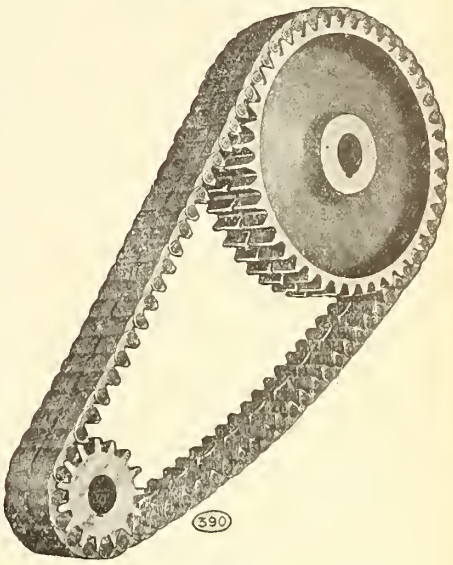
Our first drive was installed to replace a 12 in. belt which was giving us trouble on account of short centres; this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing; this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears and this has been so successful that we are now installing two more similar drives.

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drive in operation.

—The above comes from one of the largest manufacturers in Montreal and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.



Write for particulars.

Sullivan Stope Drill in a copper mine

STOPING

raising, or upper hole drilling for any purpose will cost you least pe foot of hole, or per cubic foot of ground removed, if your drills ar

Sullivan "DA21" Stopers.

Mine Managers who have conducted severe tests with Sullivar Stopers and with other makes, will tell you that this is so. They wil tell you, too, that **great speed, high power economy,** and **remarkabl freedom** from **breakage** and **wear** are factors in accomplishing thi result.

Runners will tell you that the "DA21" works more **smoothly** an with **less jar** and **vibration** than other tools; also that it is easy to clea and care for because it contains **no screw joints,** and every part can b reached by loosening three nuts.

We want to tell you more about **what** this drill is doing and **how** it is able to do it.
May we send bulletin "660 D?"

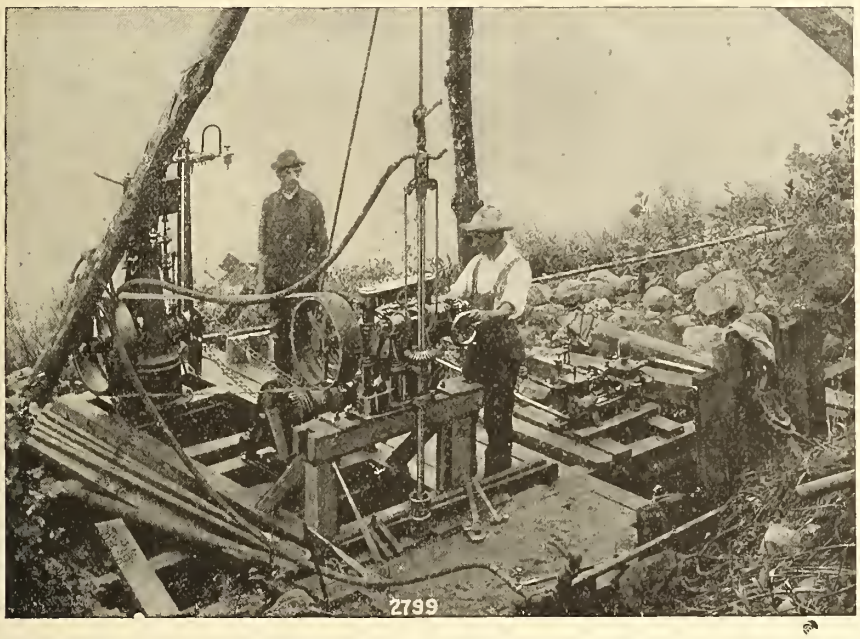
DIAMONDLESS CORE DRILLS



The "Davis Calyx Core Drill" has practically no limitations. It is the most practical, economical and reliable core drilling outfit on the market.

It will bore to any depth required; in any formation, either hard or soft; will remove any size of core; is reliable, rugged and powerful.

The machine was originally designed for economy, and has fulfilled these requirements to the last degree.

While the Davis Calyx Core Drill is distinctly portable, no element of reliability has been sacrificed to gain compactness. Each item is driven individually by belt, thus if the cutter should stick while operating, the entire machine is not subjected to the severe strains so characteristic of the direct gear drive. Reliability is absolutely essential as the machine generally operates in a remote district where a breakdown is fraught with serious consequences. To permit of greatest power economy in every locality, the outfit is offered with practically every form of drive, either steam, gasolene, electric, hand or horse power.

You can prospect your property with the Davis Calyx Core Drill at the minimum of expense and with the maximum of satisfaction.

Our Pamphlet 9001 on Core Drilling is amply illustrated and will be found very interesting and instructive to anyone interested in the subject.

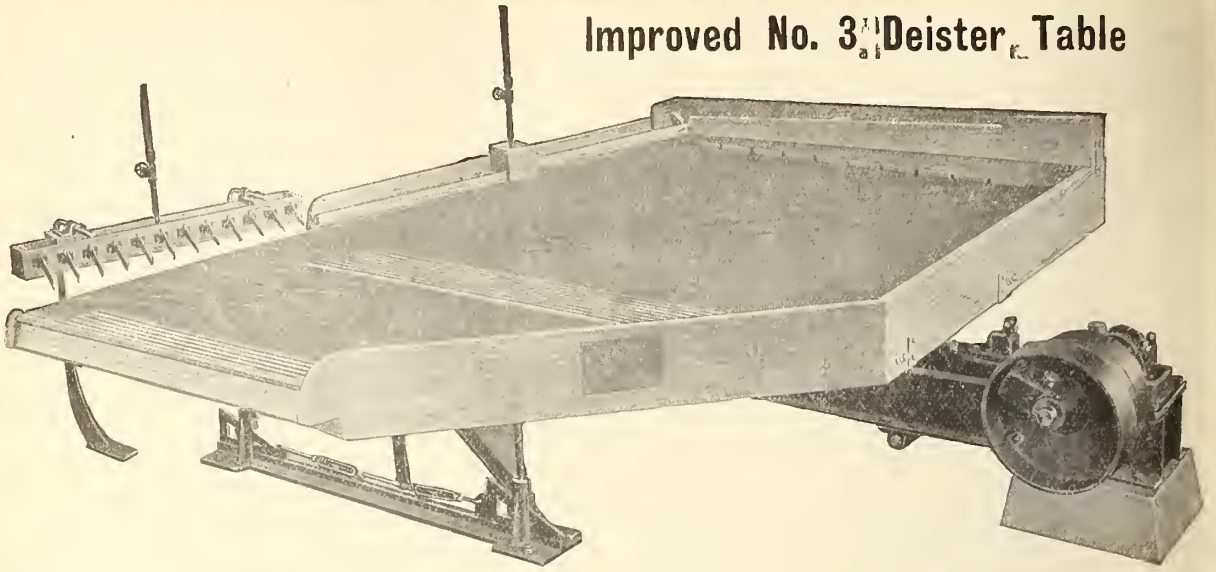
Improved No. 3 Deister Table



THE vanner has been a most efficient type of concentrating device for a decade. Competitive tests in such well known mills as **Goldfield Cons. Mines Co., Goldfield, Nevada; Miami Copper Co., Miami, Arizona; Stratton's Independence, Ltd., Victor, Colorada; Old Dominion Copper Co. Globe, Arizona** and **Detroit Copper Co., Morenci, Arizona**, have proven the Improved No. 3 Deister Table superior in efficiency on feeds of 80 mesh and finer. A pleased customer remarks: "Your No. 3 Table does as good work for us as vanners at a tithe of the cost for repairs."

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

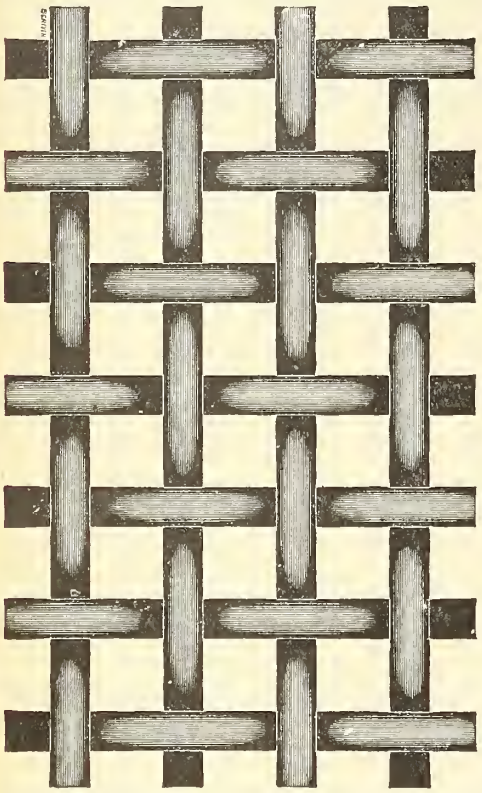
IT STANDS THE WEAR



Our Coal Screening is the kind to use where satisfactory grading of coal is to be accomplished.

Throughout every coal region in Canada.

GREENING COAL SCREENING

is daily demonstrating its superiority.

The fabric is woven of specially hard drawn steel wire from our own mills. Our method of double crimping the wires insures openings that are both square and uniform, while at the same time adding greatly to the strength of the screen, and preventing the displacement of the wires in use. We can ship Greening's Coal Screening promptly from stock, or can make screens to order with agreeable speed and accuracy.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

THE FUTURE OF MINING.

The philosophy of industrial economics is being applied to mining in increasing degree. The exhaustion of bonanza deposits and the gradual improvement of mining and metallurgical processes have brought into the category of profitable deposits many ore bodies that were not workable a few years ago. The same process of evolution is effective now and for all future time. It is wise to pause now and then for the purpose of observing just where we are and just how far we may take advantage of the progress of applied science.

The task of summing up the present status of the mining industry is not a slight one. The writer who attempts to indicate the future must be thoroughly informed as to the present. Also, he must be conversant to an extraordinary extent with the past. In the current bulletin of the Institution of Mining and Metallurgy, Mr. A. G. Charlton takes upon himself the duty of outlining the future from an economic standpoint. His paper calls for more than passing notice.

Most important factors in the expansion of mining are the increase of population, the impressive improvement in mining and metallurgical practice, and the immense growth of railroad construction. Of all parts of the British Empire, Canada has gained most pronouncedly in the last decade. In railroad construction she has taken vast strides. Her population has almost doubled. Her mineral production has been multiplied by three. And we now are on the eve of larger and stronger development.

Looking into the future effect of various natural agencies, Mr. Charlton believes that, with the opening of lower grade deposits, the cost of supplies, wage-rates, and salaries, may possibly suffer a general lowering. In this we cannot concur. The history of mining, closely interwoven with the evolution of larger and more efficient mechanical devices, teaches the lesson that cheap labour is not good labour. The general and inevitable tendency is for wages and salaries to go up. The cost of supplies is controlled by so many arbitrary circumstances that generalizations are unsafe.

A second effect, and this Mr. Charlton considers more probable, is that the supply of metals per capita may become gradually less. The price of commodities would thus fall. But we see no force in the conclusion that there would result a proportionate diminution in the number of openings available for mining and metallurgical engineers. In fact, since the price of metals would have risen, the inducements to search for good mining investments would be greater. Not until the available surface of the globe shall have been pros-

pected will Mr. Charlton's argument hold.

Five modern undertakings of world-wide significance are, in Mr. Charlton's opinion, to influence profoundly both the general channels of trade and the mining industry. These are:—The opening of the Panama Canal; the establishment of an "All-Red-Route" through Canada; the completion of the Cape to Cairo Railway; the opening of Asia Minor and Persia by the Euphrates Valley Railway; and the awakening of China to modern methods.

The opening of the Panama Canal and the completion of the Grand Trunk Pacific, not to mention the linking together of the loose ends of the Mackenzie and Mann lines, will be of most vital importance to Canada. Unlike South Africa and Rhodesia, Canada has been primarily an agricultural, pastoral, and lumbering country. Mining is only beginning to take its proper place. With efficient railroad service, mining will sooner or later become not only the chief source of freight and the indirect source of numerous collateral industries, but will on its own merits overshadow all other industries with the exception of agriculture.

Many industrial, economic, and professional phases are touched upon in the paper under discussion. These are too numerous to permit of mention here. It suffices to say that Mr. Charlton, in language that is clear and vigorous rather than elegant, clothes with fresh interest certain truths that are too often overlooked. But we must not omit an expression of approval as regards his strongly worded plea for an Imperial School of Mining and Metallurgical Economics. The suggestion that an Imperial Minister of Mines is needed "to keep the heart of Great Britain in touch with mining affairs all over the Empire" is quite impracticable. Long-distance administrative offices, as witness India, are not to be desired. Canada has had her own sad experience. In matters educational the case is quite different. We cannot have too much of the spirit of free-masonry in the mining profession.

The problem of instructing working-men has been adequately attacked only in one province in Canada, and that province is Nova Scotia. Mr. Charlton emphasizes the opinion that British working-men are under-educated and, hence, man for man not up to the productive standard of their American and German cousins. He advocates the training not only of the labourer, but also of the employer. One means to the desired end is the international collection, co-ordination, and diffusion of geological, mining, and economic data.

The point that most concerns us in Mr. Charlton's paper is one that we have often enough laid stress upon. Advancement can only come with mutual co-operation. Capital is not the main requisite. Professional enterprise, official and private interchange of information, and careful, technical control of investment are the foundations upon which mining will attain the healthiest and largest future.

CEMENT.

The direct and specific charges brought by Sir Sandford Fleming against the promoters of the ce merger must not be ignored. The person whom public believes to have been the prime mover ir whole consolidation is Mr. Max Aitken. Mr. Ai a Canadian born, is now a member of the British liament. His attainments have been widely a tised. In England he represents the typical suc ful Canadian. Thus, if for no other reason tha pediency, the charges must be investigated, and e substantiated or refuted. Of course, there are and better reasons. As a nation we require a thor re-vamping of our business ethics. If Sir Sandf allegations are true, wholly or in part, then our tish cousins have just cause to conclude that Cana are supinely willing to put a premium upon la and dishonesty, provided only that the scale of o tions be large enough.

Canadian newspapers, irrespective of politica our, are now loudly demanding a thorough inve tion. We may here allude to the fact that the adequate summing up of the cement situation app in Mr. J. J. Harpell's book, "Canadian National nomy," recently reviewed in these columns.

The Toronto Globe, May 25, comments edito upon the proposed investigation and calls vigor for immediate action. It quotes, by the way, a torial from the Moncton Transcript. It is instru to note that the Transcript has pirated, almost for word, a paragraph from Mr. Harpell's book.

On the face of things there seems to be ample g for investigation. It will be remembered tha Canadian Cement Company was organized, under inion charter, with power to issue $5,000,000 of cent. bonds, $10,500,000 of 7 per cent. cumulative ferred stock, and $13,500,000 common stock. Wit assistance of the banks the promoters purchased right a number of cement plants, a number suff to assure control of cement prices in Canada Ac ing to Sir Sandford Fleming the amount disburs purchasing eleven plants and in expenses was 592,250 in stock, bonds, and cash But the tot curities received by the holding company aggre $29,998,400. Thus there is the enormous balan $13,406,150 to be accounted for by the prom Moreover, the physical assets of the compan worth probably not more than $10,000,000. The then appears to be that Canadian consumers w called upon to provide dividends on nearly $30 000, on an original investment of one-third that

Light is thrown upon the situation by the re of the promoters, who still hold large blocks of mon stock, to the Dominion Government for the lege of converting the 7 per cent. preferred stock 5 per cent. debenture stock. Obviously by this version some $200,000 of annual dividends w transferred from the holders of preferred to the

common. And this again may be but preliminary a general unloading of common after it will become temporarily enhanced in value.

The labour cost per barrel of cement manufactured in Canada is low, lower indeed than in many countries where selling prices are more reasonable. The Canadian consumer pays as much as $2.50 per barrel. It is interesting, but not consoling, for the Canadian consumer to know that he is paying for motor-cars, English elections, and other picturesque perquisites of the promoter.

* * * *

Sir Sandford Fleming's name is known and honoured throughout the British Empire. The tactless influence of two of the Cement Company's officers in commenting publicly upon his allegations is inexcusable. Sir Sandford's word will be accepted by all until he is proved to be mistaken.

For the Dominion Government to ignore Sir Sandford's charges will be only less disastrous than for it to indulge in the not unfamiliar device of padding a special committee. The knife, and not the poultice, is necessary.

BATHS FOR MINERS.

The coal-miner suffers socially from the peculiar nature of his work. At the end of the shift he resembles a chimney-sweep. If circumstances force him to perform his ablutions in his narrow cottage, he carries dust and dirt into his home, vexing the soul of the housewife beyond measure. In settled districts he has to travel, begrimed and begriming, from the pit mouth to his house. All this is humiliating.

Dr. J. S. Haldane, in a recent number of The Times (London), writes with unusual saneness upon this subject. He expresses the belief that the question is not one of hygiene but of social decency and propriety. Dr. Haldane is a competent authority. It is his opinion that the desirability of providing wash-rooms for the coal-miner does not depend upon any point of health, but that it is entirely a matter of expediency. "The reasons that make changing and thorough washing at the end of a shift desirable are not directly connected with the health of miners, for there is nothing unhealthy about coal dust, and coal mining, with all its risks, is one of the most healthy and wholesome of occupations. The main reason is that a miner who returns home unwashed and in his pit clothes must necessarily bring into his house an amount of coal dust which is apt to soil everything and every person in the house. . . . Washing and changing at the pit-head would save endless discomfort, trouble, and dirt, and could be more quickly and conveniently done than at home. Why it has never become universal at collieries I am quite at a loss to understand."

In the course of his letter, Dr. Haldane speaks warmly of the manliness and intelligence of coal-miners as a class. His words apply equally in Canada. Here, as elsewhere, the coal-miner is usually a fine specimen of self-reliant manhood. Loyal to a degree, he is, perhaps, apt to be led away by the demagogue. But a right appeal to his better instincts rarely fails of response. He is entitled to the best and fairest treatment. It is certain that consideration in small matters, and it is a comparatively small matter to supply soap and running water, would do much to create sympathetic understanding between employer and employee. Some, but by no means all, Canadian collieries make provision in respect of washing. All coal-mining companies should be obliged by custom, if not by legislation, to consider in this respect the comfort of the worker.

A WISE APPOINTMENT.

The announcement that the services of Mr. E. Jacobs have been retained by the B. C. Department of Mines will meet with the warm approval of all Canadian mining men. For many years Mr. Jacobs has devoted himself unremittingly to the cause of clean mining journalism. As editor of the British Columbia Mining Review he did notably good work. As secretary of the Western Branch of the Canadian Mining Institute he has spared no effort to rouse and maintain interest. In these directions Mr. Jacob's efforts have been of inestimable value to British Columbia.

But it is as a general journalist that Mr. Jacobs has done most for the Province. He is the staff correspondent of the CANADIAN MINING JOURNAL. Letters and articles from his pen appear also in several of the best mining publications on both sides of the Atlantic. In the newspapers of British Columbia, notably the Nelson Daily News, there appear frequent contributions from his pen. His annual review of mining in British Columbia is singularly complete, accurate, and timely. In short, upon Mr. Jacobs the public relies for truthful and regular information as to the progress of mining in the Canadian west.

Mr. Jacobs' distinguishing characteristics as a journalist are fearlessness, exactness, and capacity for work. He has the entire confidence of the mining fraternity in British Columbia and elsewhere. His appointment to an official position will aid rather than minimize his usefulness. The Government of British Columbia has acted wisely and well in giving recognition to a man whose chief object is the good of the industry.

THE GEOLOGICAL SURVEY.

On another page will be found a statement of the proposed field work of the Geological Survey during the coming summer. Our readers will notice that the officers of the Survey are well distributed throughout all the mining provinces. The influence of economic considerations is particularly evident. For example, Dr Andrew Lawson, of the University of California, who some years ago spent considerable time in co-

ordinating the geology of the Lake of the Woods and Rainy River regions, is again to devote his energies to these districts. No better choice could have been made. We sincerely hope that Dr. Lawson's revision of the geology of this country will bear immediate fruit. Other specialists, not members of the regular staff, are Dr. Heinrich Ries, Dr. R. A. Daly, and Dr. A. F. Foerst.

It is gratifying to note that the most prominent geologists on the continent are glad to be associated with our Geological Survey. This fact is in itself a constructive compliment to this branch of the Federal Department of Mines.

Incidentally, we learn that Dr. Chas. D. Walcott, secretary of the Smithsonian Institute, has accepted an honorary position as collaborator in geology with special reference to the Cambrian of the Rockies. Thus Dr. Walcott's results will be officially available to the Survey.

On the whole, the Survey appears to be in a fit and vigorous position. Its labours bear more closely than ever upon the industry of mining, and its grip upon public interest is yearly becoming stronger. The establishment of reciprocity in brains between Canada and the United States is quite as important as tariff-tinkering.

OURSELVES.

Modesty is a virtue. Not often do we lose sight of this fact. Circumstances, over which we have occasion to feel pleased, have impelled us to forget for the nonce our inherent diffidence. This issue of the CANADIAN MINING JOURNAL is larger by eight pages than former numbers. The pressure upon our advertising pages has become so great as to necessitate four additional pages. As a consequence we have added four more to our reading matter. This, we hope, will be as gratifying to our readers as to ourselves.

Having divested ourselves for a moment of our garment of modest reticence, it may not be unseemly to say a few words about the JOURNAL as an advertising medium.

Unlike the so-called trade periodicals, the JOURNAL does not appeal solely to one class or profession. It is true that our steadiest support has come from subscribers and advertisers who are entirely or almost entirely identified with the mining industry. But in addition the JOURNAL'S list of subscribers and advertisers is widely inclusive of many diverse interests. Our subscribers are scattered over the wide world. Japan, Corea, Russia, Germany, Central and South America, all appear upon our mailing list. All the countries of Europe are represented. But, after Canada and the United States, Great Britain and the remainder of the British Empire receive the largest share of copies.

The Canadian market for mining machinery, supplies, and specialties, not to mention professional talent, is singularly active. The bulk of our readers are men who are in that market for some commodity has to do with mining, whether it be machinery brains. Hence we feel that, without boasting, we claim to occupy a unique position in that the JOU is the only periodical that can appeal adequatel the large number of persons whose business in li to buy or sell the materials that are necessary to operation of mines.

THE SPRINGHILL STRIKE.

After long years of violence, recrimination futile waste, the Springhill strike is at last en Never in the history of mining in Canada has t been a more acrimonious struggle. The points of ference, and the nature of the dispute, changed every passing year. But each year brought its accretion of bitterness and hostility.

For twenty-two months about 1,200 men have idle. This is but a fraction of the total loss thro out the past. But it is probably the largest single i

Peace has been secured. We are glad to note the U.M.W.A. has not won recognition, because U.M.W.A. does not deserve recognition. The P.W is a far healthier, and sounder organization, and i digenous to Nova Scotia.

PORCUPINE.

In our advertising pages will be found annou ment of a forthcoming book on Porcupine. As forth there, the demand for back numbers of the ADIAN MINING JOURNAL containing articles on Po pine could not be met. Hence the publishers fel pelled to bring out an adequate edition of a book would include most of the published articles, a with some new and appropriate material. Very tunately, also, through the courtesy of the On Bureau of Mines, it has been possible to secure latest official geological map of the district. Thi cellent map is remarkably complete and accurate is in itself an absolute necessity to the prospector miner. It must be noted that the Bureau gives no cial sanction to the material in the book. The ma copyrighted. As an act of courtesy the Bureau permitted us to secure a number sufficient for the ent book. But this implies nothing more than mere fact that the map appears with our book.

The book is so arranged as to give the reader al present available authoritative information that i quired to guide him in learning about Porcupine. or two general articles are included for the benef the untechnical reader. Late claim maps and a directory of companies are useful additions.

We sincerely hope that the volume will serve purpose for which it is designed.

The Yukon navigation season has opened. The steamer from Dawson for Iditarod was booked to on May 30.

Construction of 110 Koppers By-Product Regenerative Coke Ovens for the Algoma Steel Company at Sault Ste. Marie, Ontario, Canada.

By D. M. GRIFFITH.

On March 11th, 1911, the first coke was made in No. 1 battery of the 110 by-product coke ovens, which were constructed by H. Koppers, of Joliet, Illinois, for the Algoma Steel Company at Sault Ste. Marie, Ontario, Canada. Less than a year elapsed from the time excavation was started until the ovens were producing coke; and considering the extreme conditions under which this plant was built, such as severe weather, marshy ground, poor labour conditions, isolation of plant from base of supplies, working from temporary yard level, etc., remarkable progress was made in its construction.

Fig. 1.—Part of the Piling Used for Carrying the Concrete Slab. Photograph taken April 5, or 15 Working Days after Excavation was Started.

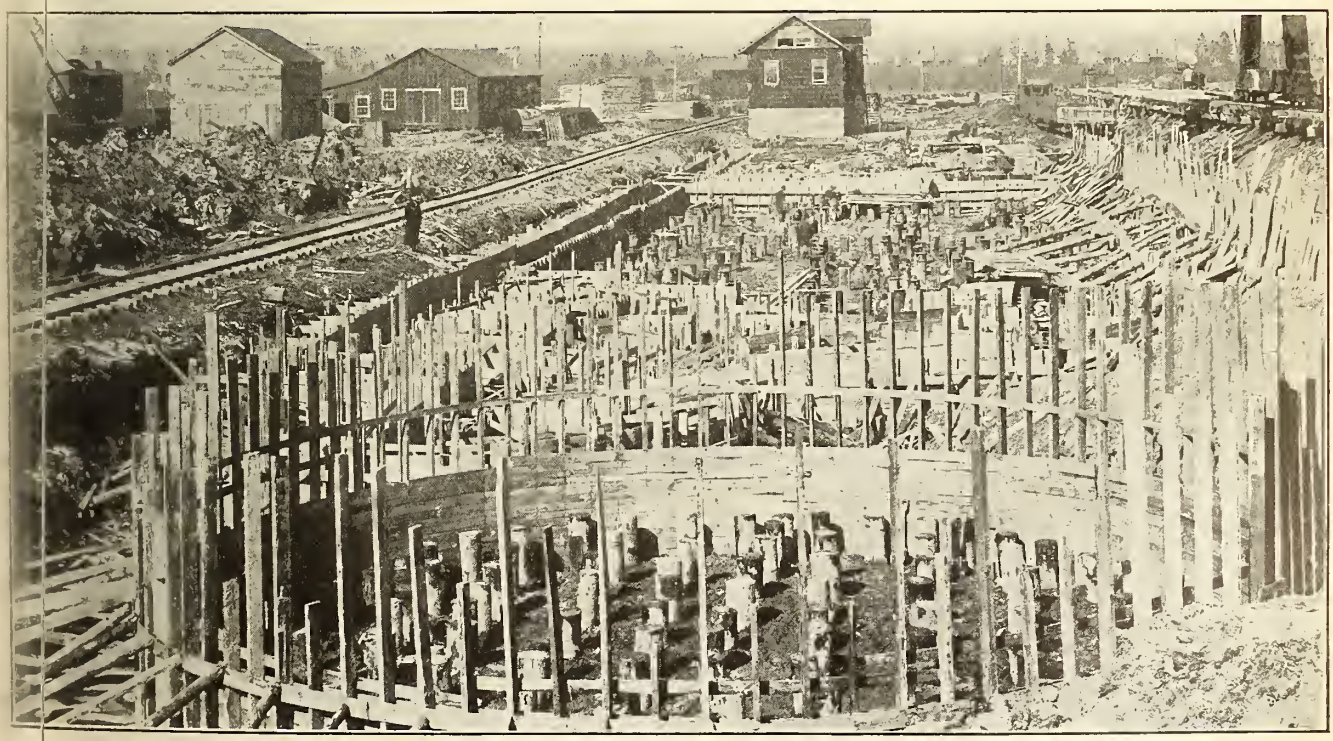

Fig. 2—Progress of Piling and Form Work in 19 Working Days, or up to May 19.

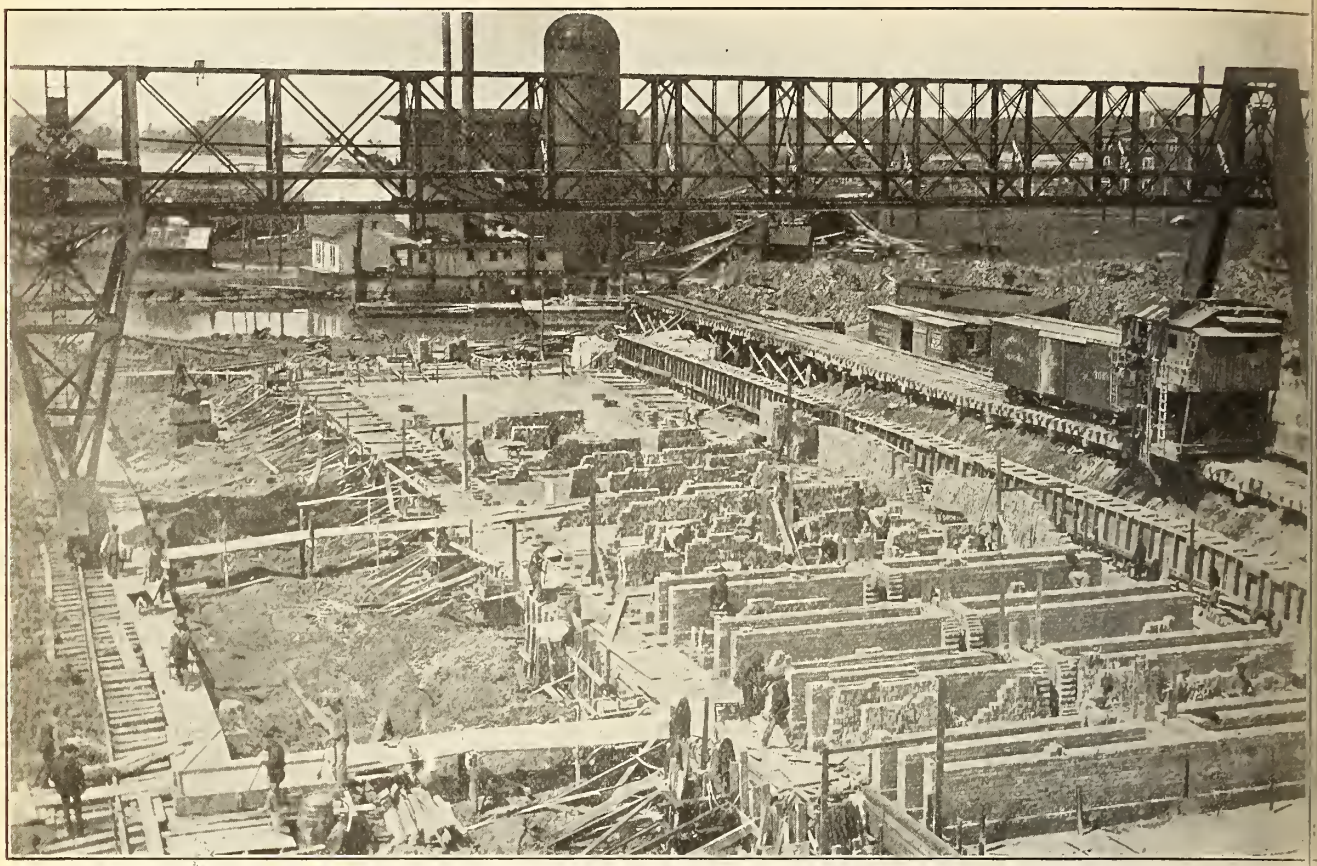

Fig, 3—Oven Foundations and Chimney Flues to Stack, with Brick Work on Regenerator Walls under way.

On account of the marshy ground at the site chosen for the coke plant, it was necessary to support all of the foundations upon piling. The total number of piles required was about 6,020.

To divert the course of a creek which wound around through the coke plant site, two concrete retaining walls were constructed. One of these walls was of sufficient size to support the track for the shea of the travelling coal bridge. This creek now ext the entire length of the coke plant, and empties the slip just beyond the stack end of battery No.

The slip was extended about a half mile, so

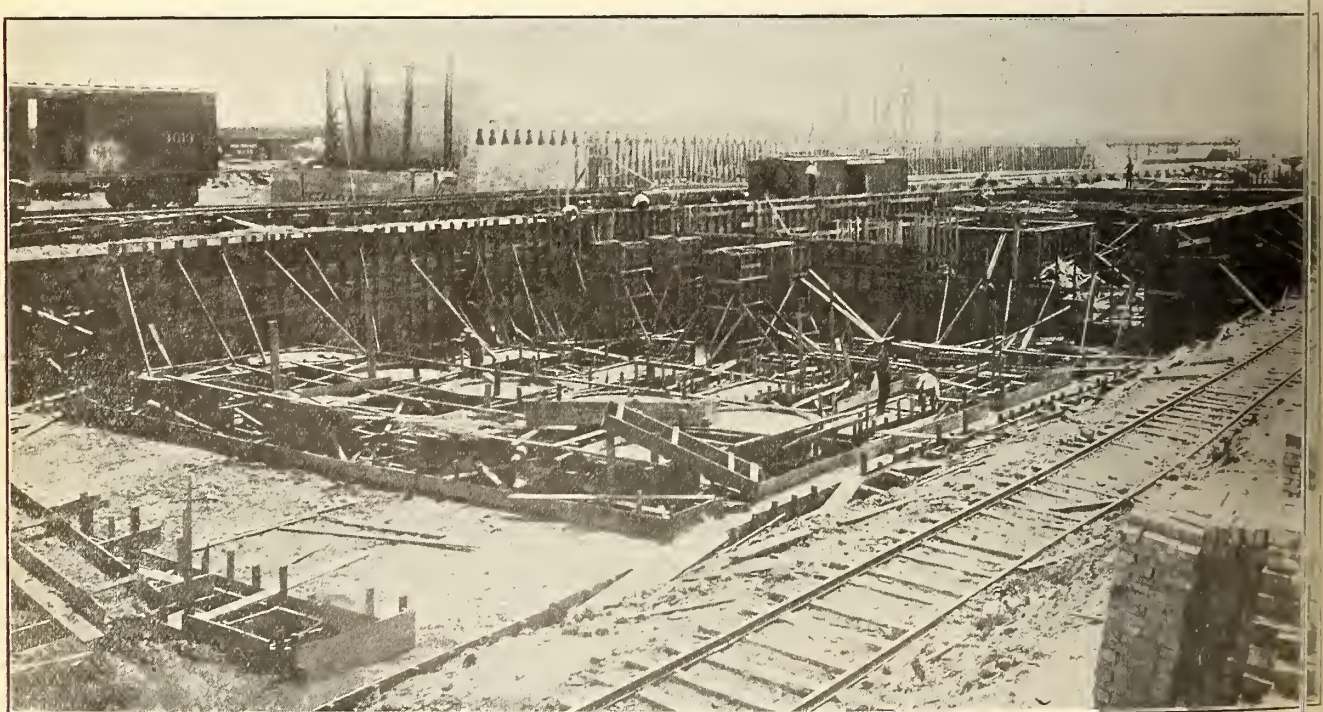

Fig: 4.—Showing the large Amount of Concrete and Form Work completed in 37 Working Days Following the view in Fig.

could be delivered direct to the coke plant by This channel is 90 feet wide and is of sufficient to take care of boats with a carrying capacity 2,000 tons of coal.

conveyed, by electrically operated coal transfer cars, to either the coal storage pile or to the coal hoppers.

The coal is taken from this hopper by a belt, to the coal breaker and crusher building, where it is

Fig. 5.—Showing by Height of the Locomotive the Large Amount of Form Work needed to give a Yard Level 16 Feet above Top of Piles.

Fig. 6.—Progress Made up to October 6, 1910.

connection with this slip, and extending its entire length, has been constructed a very substantial timber dock. This dock supports the track on which the coal unloaders travel, also a coal transfer trestle, by means of which the coal from the boat unloaders is broken up and the iron particles removed by a magnetic separator. The coal is then crushed and conveyed by a belt to mixing bins, from which point it is conveyed by another belt to the 2,000-ton coal storage bin. By means of hand operated gates, which are lo-

cated in the bottom of the coal storage bin, the coal charging car receives the coal from the bin for charging direct into the top of the ovens.

In fig. 1, which is shown on this page, can be seen a part of the piling which is used for carrying the concrete slab, upon which the oven and stack foundations

5, 1910, which was just fifteen working days a the excavation work was started.

Fig. 2 shows the progress made in the construct work on No. 1 battery up to May 7, 1910. In 27 wo ing days, the form work for the voids and chim flues was completed, and the 3-foot thick conc

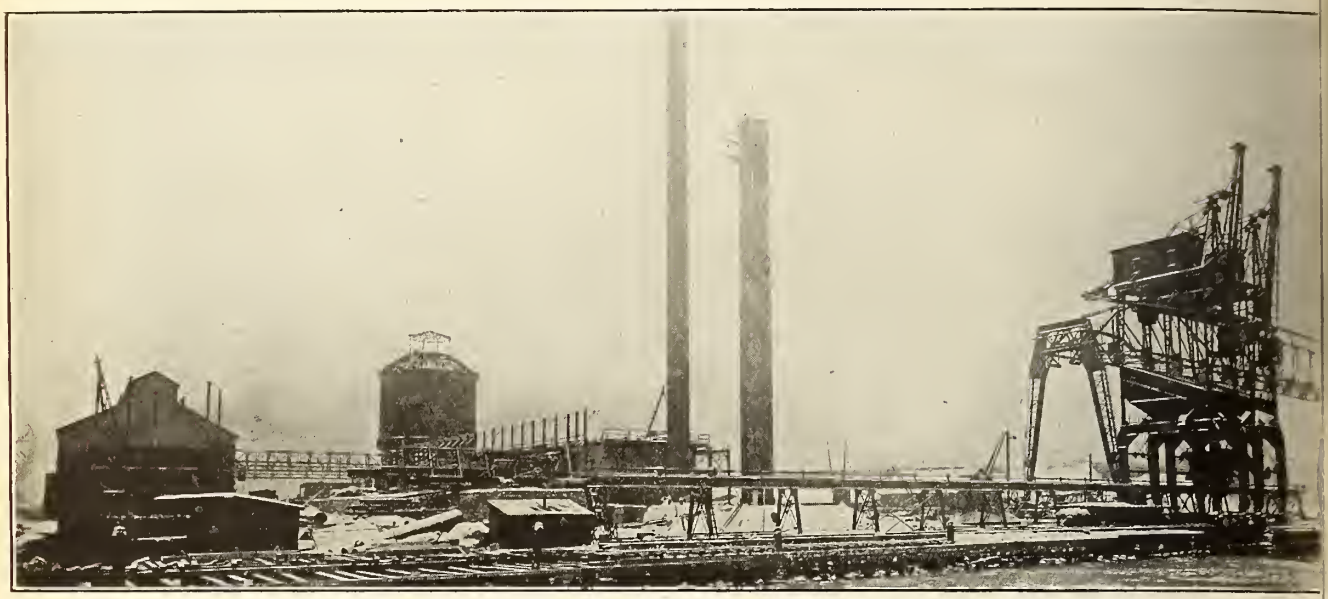

Fig. 7.—View taken December 7, 1910. showing Slip, Coal Unloaders, Coal Transfer Trestle and Storage Bin, By-Product Building and Battery No. 1, with Stack and Gas Holder.

Fig. 8—Temporary Building over Battery No. 2. Brickwork for This Battery Nearly Completed.

are supported. These piles vary in length from 30 feet to 60 feet, and are spaced about 2 feet 9 inches, centre to centre. The steel travelling bridge, in the background, is used for distributing the concrete for the oven and by-product building foundations and the creek retaining walls. This picture was taken on April

slab, which rests on the piles, was laid. Also, the c crete foundations for the entire first battery were p to an elevation of 11 feet above the top of the p s. This left a height of about 5 feet more of concret o be put in, to bring the oven foundations up to he proper level for the starting of the brickwork.

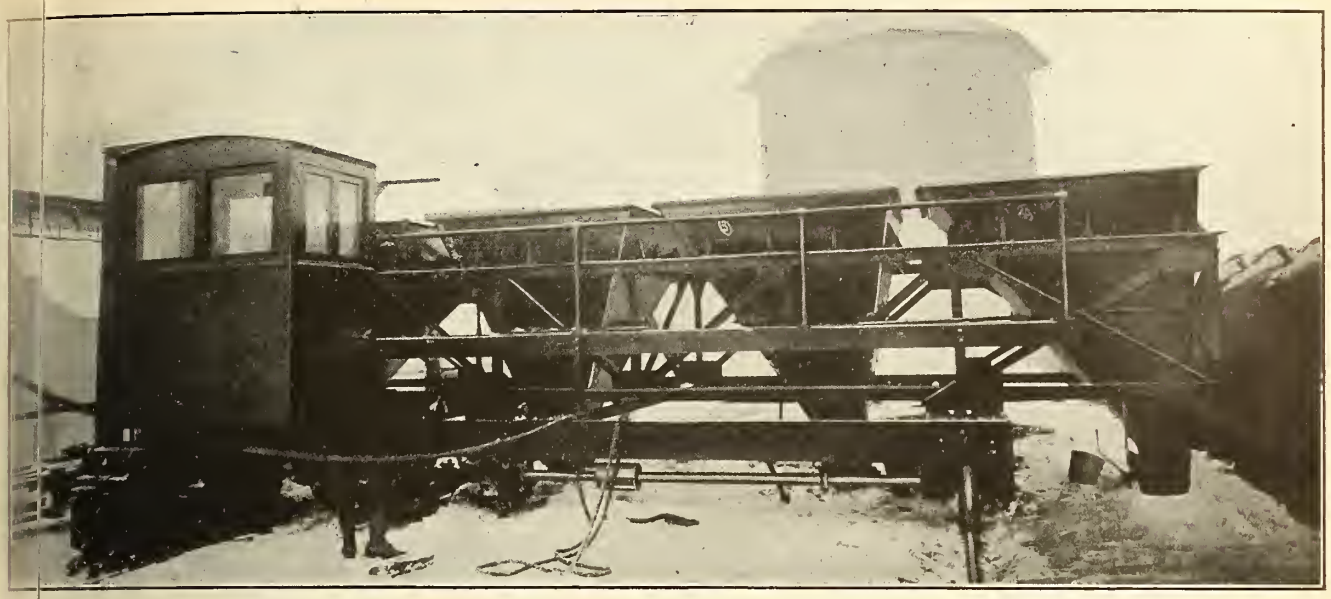

Fig. 9—Electrically Operated Four Hopper Coal Charging Larry.

On April 26th, excavation work was begun for the by-product building and gas holder. In fig. 3, can be seen the progress made in piling and form work, up to May 19th. In nineteen working days all of the excavating and piling for the foundations for the by-product apparatus, building walls, and gas holder was finished, as well as considerable form work for gas holder and building walls.

Fig. 4 shows the progress made in the construction work on the ovens, up to June 8th. This picture was taken just one month later than that shown in fig. 2, and it will be noted that the oven foundations have been finished, and the chimney flues to stack have been constructed and lined with brick; and a good start has been made on the brickwork of the regenerator walls. In the background can be seen the progress which has been made on the slip, up to this date. The channel has been dredged for a distance of about one-third of a mile, and has reached a point a little beyond the centre line of ovens.

In fig. 5 can be seen the excavation and piling for the creek retaining walls, between which will flow the creek, whose course was diverted.

Fig. 6 shows the progress made on by-product building form work and foundations up to July 2nd. It can be seen that a large amount of concrete and form

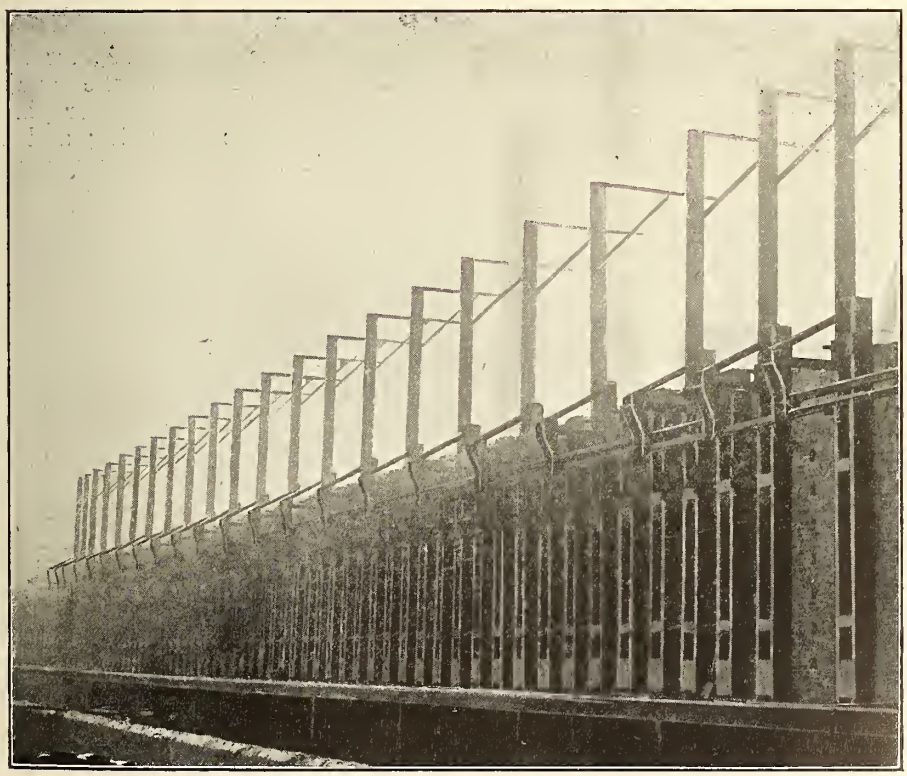

Fig. 10—Progress on Battery No. 2 up to March 1, 1911

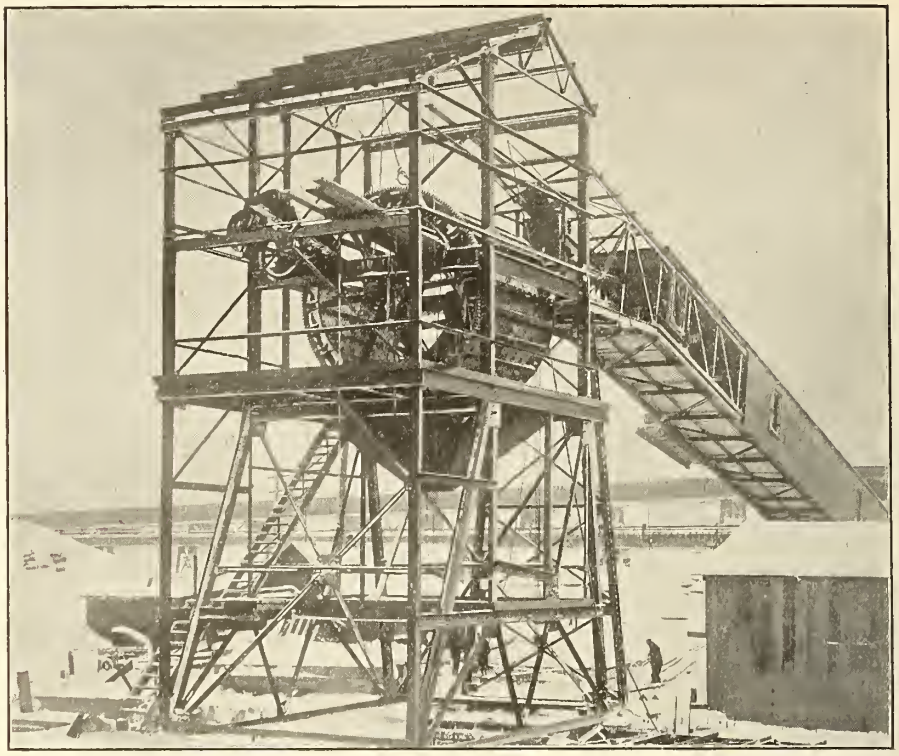

Fig. 11

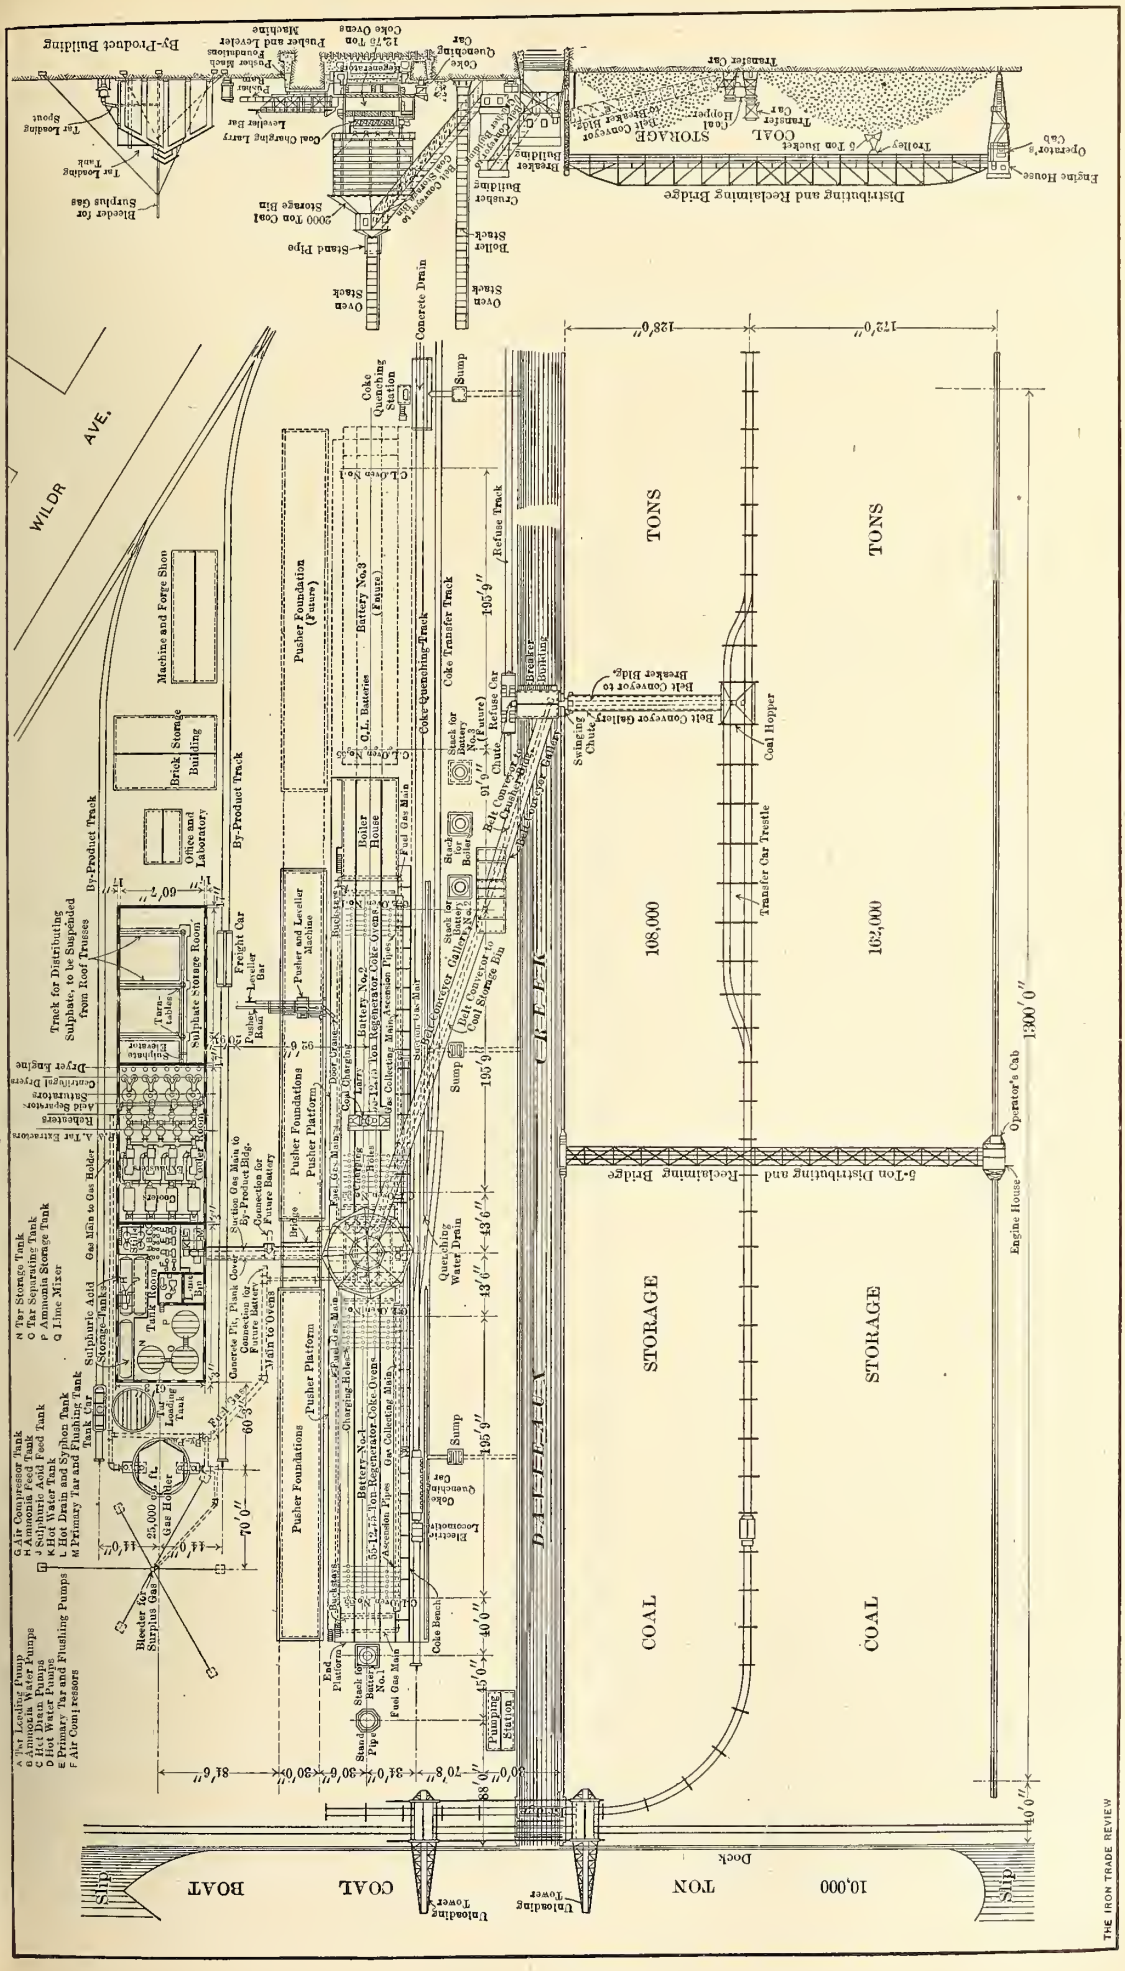
work has been completed during the interval of 37 working days, whieh elapsed between the taking of the photographs, shown in figures 3 and 6.

Fig. 7 shows the amount of eonstruction work that has been done on the ovens and by-product building, up to August 13th. The regenerator walls have been finished; the oven wall brickwork has reaehed a height of about 4 feet above the floor of the ovens, and the concrete pinions and end buek-stays have been erected at eaeh end of the battery. In comparing the height of the form work of the by-produet building, with that of the standard loeomotive, shown in the foreground, one can readily see that a large amount of eonstruetion work was neeessary at this point to bring the foundations to their proper elevation, so that the finish yard level would be 16 feet above top of piles.

Fig. 8 shows the progress made up to October 1910. The brickwork has been completed for batte No. 1. In the foreground is shown a part of the fo work and eonerete for battery No. 2. The steel r trusses and eolumns for the by-product building erected, and work has been started on the purline a building walls.

Figure 9 shows the progress made up to Nov. 1910. The buekstays, eoke and pusher side st benehes, with east iron eover plates, steel stack, a supports for gas collecting and suction mains ha been ereeted. The regenerators are filled with check

Fig. 12



General Arrangement of Koppers By-Product Coke Ovens at the plant of the Algoma Steel Company, Sault Ste. Marie, Ontario.

brick, the regenerator end walls have been bricked in; and the brick walls underneath the benches have been completed.

Fig. 10 shows the slip, coal unloaders, coal transfer trestle, dock, travelling coal bridge. standpipe, pump house, stack for battery No. 1, coal storage bin, by-product building, battery No. 1, and gas holder. This photograph was taken on Dec. 7th, 1910.

Fig. 11 shows the progress made on battery No. 2 up to Dec. 15th, 1910. The foundations for the coke pusher and levelling machine have been finished. The oven brickwork for the entire battery has reached a height of 8 feet above the floor of the regenerators. The large temporary building is used to protect the brickwork and workmen during the severe cold weather, and has been completed with the exception of the side sheeting.

Fig. 14 shows the progress made on a part o coal handling machinery up to Jan. 6, 1911. The framing for the breaker and crusher building, an conveyors from the coal hopper to breaker buil have been erected and work has been started o erection of the breaker machinery.

Fig. 15 shows the electrically operated 4-h steel coal charging larry on top of battery No. 1. car receives its coal from the coal storage bin an a capacity of 12.75 tons, which is sufficient to c one oven. In the background can be seen the 2,00 steel coal storage bin which is located between ba No. 1 and battery No. 2. This photograph was Jan. 10th, 1911.

Fig. 16, the photograph which was taken fro pusher side on March 1, 1911, shows the pro which has been made on battery No. 2. The

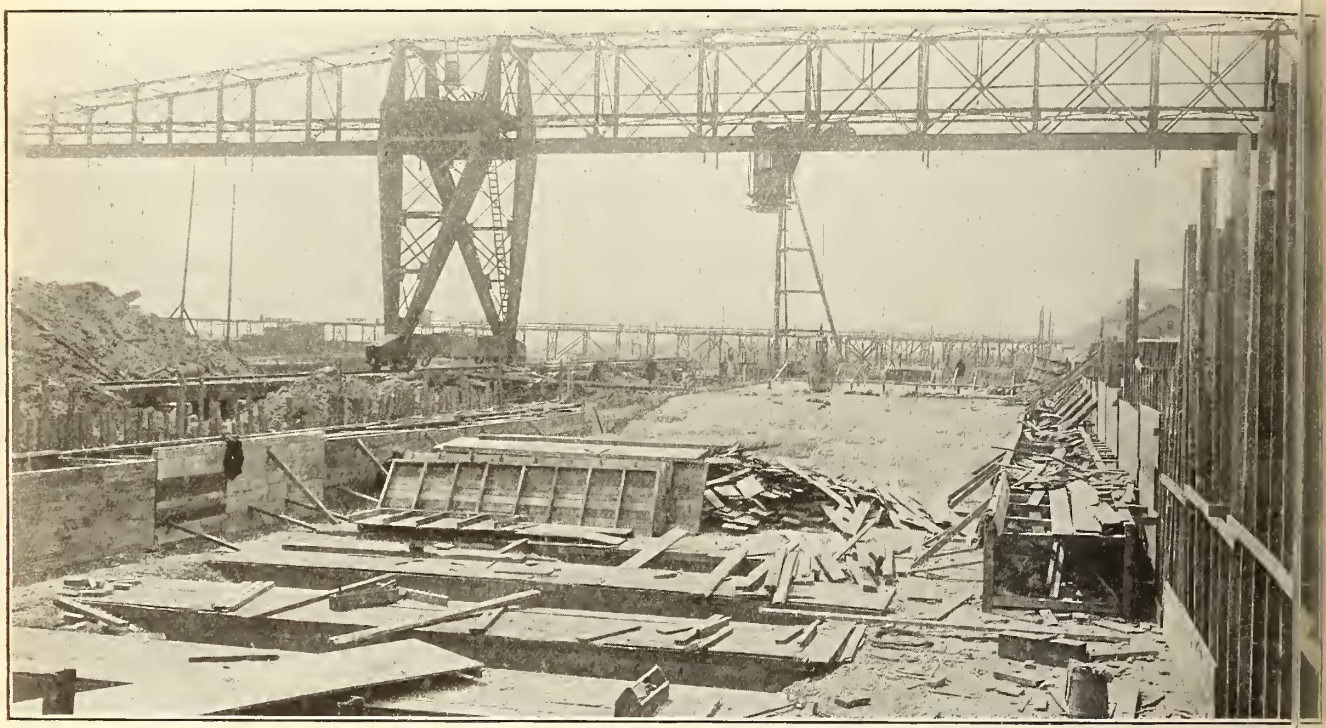


Fig. 12 shows an interior view of the boiler house, which is equipped with three 300 h.p. Babcock & Wilcox boilers. The boiler house is located at the extreme end of battery No. 2. This photograph was taken on Dec. 28th, 1910.

Fig. 13 shows an interior view of the temporary building over battery No. 2, photograph of which was taken on Jan. 16th, 1911. The brickwork here shown is above the roof of the ovens and nearly completes the brickwork for this battery.

work, including the regenerator end walls an checker brick has been finished, and the bucksta structural work on coke and pusher benches hav erected.

Fig. 17 is a general arrangement of the entir plant, showing the present installation of two ba of 55 ovens each; and provision made for a fut stallation of one battery of 55 ovens.

Battery No. 2 will be ready to make coke by 24th.

THE PORCUPINE MINING DISTRICT

Introductory Remarks reprinted from text of Canadian Mining Journal's New Publication.

The first press reports about Porcupine were received with the silent skepticism that is born of experience. The unfortunate history of Larder Lake—a district, incidentally, that has never received fair play—was too fresh in the memory of mining men to permit of enthusiasm being roused. Thus the pioneers of the Porcupine district were left for some time in splendid isolation.

While this was wholesome morally, it was couraging. The nomadic prospector depends u public to pay his shot. He has no desire to op he merely wishes to discover, to make his "s and to have done with it. In Cobalt he did t Porcupine he found the situation much more cated. The investor had a bitter taste in his and did not intend to be guilty of certain indis

marked the birth-throes of Cobalt. Nevertheless, number of ready sales took place. Companies and dicates were organized post-haste, and the pro- ers did not suffer. But in the greater number of s the investor held aloof. The consequence has that the majority of Porcupine flotations have engineered with a view to taking in immediate its. This phase is remunerative to the individual, most costly and unbusinesslike so far as Porcu- is concerned.

obalt, when it was discovered, met with a very l reception from mining men. As soon, however, actual shipments of ore were made, recognition e with surprising rapidity. Then followed a per- during which those whose judgment had been at t sought to vindicate themselves by throwing cold er on the camp. But Cobalt, despite all captious ics, made good.

obalt brought into play much more prospecting mining talent than could well be taken care of. ce it was natural that many individuals should k new fields. New fields were sought and were nd. Porcupine was the first fruit.

its first position Porcupine was between the deep of popular incertitude and the devil of promoters' bast. As to the real character of the ore bodies e was room for scientific discussion. But the at- sphere is now clear, at least geologically. The mpt and effective work of the Ontario Bureau of es was of inestimable value to the camp. The ad- t of substantial foreign interests is to be credited he Bureau's timely activity.

o vigorous was the early prosecution of mining in cupine that the Ontario Government decided to d to the camp a branch line of the Temiskaming Northern Ontario Railway. This line will be fin- d during the coming summer. Naturally it will n much to the district. Only those who worked r way over the summer trail last year can realize severely Porcupine operators were handicapped the lack of transportation facilities. The fact that ns were hired for as much as $25 per day gives e idea of the situation. But by far the worst ob- le was the bad mail and telegraph service. The gent terms imposed upon buyers made it almost ossible to investigate mining claims sufficiently. It readily be imagined that a delay of one or two ks in transmitting a letter from Porcupine to To- to, Montreal, or New York might imply the differ- between success and failure in putting through a ing deal. In any case, the general tendency would o come to a decision that was unwarranted by ex- ng conditions. Now, however, since Porcupine will e all the advantages of modern communication, it ntirely possible to investigate fully any claim. This temper the tone of promotion.

* * * * *

ntario has had a very bad name in gold mining. contributing factors in this bad name are too merous to mention. But the prime fact is that the d mines of the province have never been worked their own merits. There has been far too much ming and promoting, and far too little ready money common-sense. The Lake of the Woods region, instance, had much to recommend it. Probably day money could be made out of several of the properties that have been labelled failures. But the district has lost favour in the eyes of prospectors and operators. This is true of more than one gold-mining section of Ontario.

Except for the Yukon excitement, no such widespread interest has ever been stirred up in Canada by the discovery of gold. Quite apart from any direct profits that may accrue to operators in Porcupine, the advertisement to Canada generally and to Northern Ontario specifically, is of enormous value. Following so closely upon the exploitation of Cobalt, the opening up of Porcupine has kept Northern Ontario continuously in the lime-light. It has strengthened decidedly the belief that there are yet many prizes to be won in the hinterland of Ontario and the adjoining area in Quebec. An illustration of this is afforded by the large amount of staking that just now is being done on the territory surrounding Keekeek Lake, Pontiac County, Quebec. Humanly speaking, it is improbable that attention would have been paid to this remote spot for some time to come had it not been for Porcupine.

Study of the mining situation, in Ontario, brings the conviction that only the fringe of the northern mineral belt has been touched. The summer of 1911 will see more prospecting done than ever before. Succeeding seasons will bring more men and more money to the country. It is absolutely within the range of probabilities that other Porcupines will be discovered. If Porcupine lives up to its promise, then Ontario will have received an unprecedented commercial impetus. Moreover, the wave of development will spread through to Quebec. Farming will follow hard upon the heels of mining. Thousands of square miles of arable land will be thrown open to the farmer and a permanent population will be established.

Considering the large number of bona fide investments that have been made in Porcupine, it behoves mining men to do what in them lies to disseminate right information and to discountenance the wild tales that emanate from all irresponsible sources. In whatever way Porcupine may develop, it now seems that in a few mines money will actually be made. But many more may prove profitable if initial sales and promotions are handled decently. In other words, sane exploitation will give the camp a maximum chance; frenzied speculation will shorten the life of individual mines and will injure the camp permanently.

* * * * *

The demand for back numbers of the CANADIAN MINING JOURNAL containing articles on Porcupine has exhausted all available supplies. As that demand shows no signs of abating the publishers of the JOURNAL decided to issue in pamphlet form several of these articles along with other material. The geological map that goes with this book was secured through special arrangement with the Ontario Bureau of Mines. The map has been copyrighted by the Bureau. It is to be noted that the Bureau assumes no responsibility, direct or indirect, for the matter contained in this book. The publishers, however, wish to express their warm sense of gratitude to the Bureau for the courtesy extended.

It is hoped that the information contained in the succeeding pages will prove a useful guide to professional men and investors.

PROGRESS IN MEXICAN MINING AND METALLURGICAL METHODS DURING THE CENTURY OF INDEPENDENCE

(Continued from last issue.)

The proper proportion of common salt is then added to the torta and thoroughly mixed with the pulp (repaso) by the action of 24 horses, held on lines by the "tortero," round whom they circle, while he himself continually changes his position, so that all parts of the torta are eventually reached. Before 1793 this work was done by hand. The next operation consists in the admixture of "magistral," an impure sulphate of copper obtained by the calcination of copper pyrites containing variable quantities of iron. Lastly, the torta is incorporated, that is, mercury is spread over its surface in a fine spray produced by filtration through porous cloth. After each addition of ingredients, and afterwards every other day, a repaso is given. In from 20 to 30 days, according to the size of the torta and the weather, the chemical action is complete, and the torta is said to be "rendida." The silver and gold has combined with the mercury to fluid amalgam, from which the pulp is washed by a liberal addition of water and stirring in large cylindrical vats. It is now only necessary to filter the excess of mercury off the solid amalgam, distill the latter in the manner described before for the gold amalgam, and melt. The product is very pure. Its fineness is determined in the mint and expressed in thousandths of the gross weight. Impurities are deducted and it should be noted that if gold is present in less proportion than three one-thousandths, it is not only not paid for, but even deducted from the silver as an impurity. Small wonder that Mexican pesos of this period from the gold bearing districts, are subjected, at a good profit, to parting in London and Paris.

The patio process is a purely empirical one and requires great practice on the part of those who carry it out. It would lead us too far were we to attempt a detailed description of all the operations in connection with it, or to mention the various vicissitudes to which a torta may become subject, and the means for diagnosing and correcting them. The only guide for the "azoguero" is that afforded by frequent tentaduras. From time to time improvements, based upon chance discoveries, have been introduced and local modifications, demanded by peculiarities of the ore, have been made, but the history of the process is free from the often absurd nostrums frequently used during the earlier times of Californian panamalgamation. Altogether, Medina's discovery was an admirable one and much more perfect than the mining methods in use at the beginning of the 19th century, which have been described above, for no other process until the advent of cyaniding has been able to oust it.

We have tried to produce an impressionist picture in broad traits of the methods employed in Mexican mining and metallurgy at the beginning of the century, in the years immediately preceding the outbreak of the revolution which ultimately liberated the country from the oppression under which it had been ground for more than two centuries and a half. It was the most productive period of Mexican mining with which the general prosperity of the whole country had naturally kept pace.

Then came the revolution, and with it almost c plete stagnation of the industry. Guanajuato, a city of 100,000 inhabitants, had most to suffer from depredations of the contending parties, and besi other material losses, had to face the almost comp destruction of its principal industry. The popula dwindled down to barely 14,000; work in the mi became paralyzed on account of the impossibility procuring workers, and the necessary fodder for great number of animals required in the operati Unwatering of the mines had to be abandoned an many mines the water rose to the level of the bocam In others, which were not wholly submerged, explo tion was confined to the scrapings of the upper w ings for the ore which had been overlooked in m prosperous times. The production fell to one-qua of what it was in the years immediately preceding revolution. While in the great Valenciana mine extraction in 1808 had a value of $1,523,000, it dw led down in 1823 to only $36,200. In one word, mi was at its lowest possible ebb, and what was e worse, the spirit of enterprise had been crushed the means for recovering the lost position were utt wanting.

The first relief from this apparently hopeless c dition of affairs came from a quarter to which at present day we hardly give sufficient credit for timely help which it afforded, even if it was actu by motives of self interest.

The country, after having shaken off the Spa dominion, was now open to the whole world, and E lish capital was the first to appreciate the opportu for engaging in profitable mining undertakings Mexico. One company acquired the Real del M properties in Pachuca from the Count of Regla. Ot took in "avio," the most important mines in Gu juato, as well as in other parts of the country. Thro ignorance and inexplicable negligence on the par the local representatives their operations were l financial failures, and after spending large sum endeavours to retrieve their fortunes, they had to tire from the field with enormous losses to the sh holders. While we cannot commend these compa for intelligent management, or for signal improvem in the method of working, it is undeniable that bringing large sums of money into the impoveris country, which were mostly expended in the unwa ing of the mines, they gave the first impulse tow a renewal of interest in mining, collected the scatt mining population, and in other ways prepared road over which the original owners afterwards velled towards prosperity.

On the whole, while mining in the years follow again became highly profitable, no improvement importance took place for a long time. Among older members of our Institute there are still many have been eye-witnesses to the crude methods in v before the period of Mexican independence as they l been described above. However, gradually pr chemical methods for determining the nature and ness of ores took the place of the former tentad

mite was substituted for black powder; rock s came into use and the raw cowhide with its con- tants was more and more relegated to the back- nd. (2) This progress is due in great part, to ntelligence, adaptability and perseverance of the nal engineers who received an admirable training he mining schools. But they had to contend st powerful enemies: First, the fact that the coun- was far removed from machinery producing cen- and that the means of transport were insufficient he conditions for industrial independence, namely o fuel and iron, were as yet lacking. Then deep- d habits of indolence and improvidence of the la- ing classes had to be overcome, and we all know time is a necessary condition to effect reforms is respect. And finally, there was the egotistical ide of the monied classes towards mining. The pirit of their fathers had departed and the capi- as diverted from the mining industry to be in- d in undertakings which offered results without ecessity of personal application.

e repeat, the progress made up to the end of the entury was slow, and Mexico stood in danger of surpassed, notwithstanding its enormous mineral h. by other nations either more enterprising or favourably situated with regard to fuel.

en the situation suddenly changed. The discovery made that in the numerous streams descending the central tableland towards both coasts, an mous source of power was contained which could nverted into electric energy and conveyed, with- reat loss, to the important centres of industry.(3)

u are acquainted with the stupendous undertak- n the valley of Necaxa, at least in its effect on in this capital. But its bearing on the develop- of the mining industry can hardly be realized by not directly connected with it. The wonderful ity displayed in such mining centres as Pachuca, ro, Guanajuato, and others, would be impossible, any rate greatly handicapped, if coal had still used for the production of motive power. Not to ion the total insufficiency of the power to be de- from the work of mules and horses. All the ani- at work in the Guanajuato mines and mills dur- its most prosperous period could, during a e month, not supply the energy required for the of a single day. It may therefore be truly said the advent of electricity marks a most important h in the history of mining and that Mexico in con- ence of its unusually favourable hydrographical itions has derived more benefit from the applica- of this agent, which but yesterday was scarcely n, than any other country. Instead of suffering scarcity of fuel we have suddenly attained the ion of possessing unusually cheap mechanical r.

nother discovery which gave an immense impulse Mexican mining was the method of extraction of recious metals from their ores by means of weak ions of potassium cyanide. There has been much roversy over the question as to who was the real verer of the principle underlying this operation. shall not enter into it here. Uncontrovertible, ever, is the fact that since the introduction of the ess by the McArthur-Forrest interests, millions of of ore, which formerly had to be considered as of alue, can be treated profitably, in consequence of h the economic conditions of the mining industry been radically changed and much foreign capi- has been attracted.

Mexico was somewhat slow in adopting this method, possibly on account of the fact that as at first practised, it was more applicable to gold than to silver ores. (4).

In our description of the process we can be much more concise than we were in that of the earlier methods, if for no other reason than that Rayas in 1808 is immeasurably farther from us than, for instance, Pachuca in 1911. Any of the modern reduction works there can be readily visited by those desiring some knowledge of this newest branch of metallurgy of the precious metals. Such a visit will afford convincing evidence of the great importance of this method of ore treatment and will show that, while Mexico entered on the field long after other countries, once the start was made, it has not only kept pace with them but, certainly as regards the treatment of silver ores, is ahead of most.

Briefly, the process is carried out as follows: as in any other wet method of extraction, the ore is finely triturated in stamps, chilean mills and tubemills, cyanide solutions being added from the beginning. The separation of sands from slimes, which a few years ago was considered indispensable to successful cyanide practice, has been superseded in all modern plants of this country by the "all sliming" method in which the sand is all ground as fine as possible or rather as fine as necessary, to obtain the best economic results. The pulp, consisting of finely ground ore and cyanide solution, is then agitated by means of mechanical stirrers or by compressed air, the latter now being made the rule in Pachuca. When the cyanide has completed its chemical action on the gold and silver of the ore, these substances are found in solution as double salts with sodium cyanides. This solution must now be separated from the worthless tailings by means of vacuum or of pressure filters of various construction, of which new forms are almost daily brought out. The clear filtered solutions are then brought into contact with zinc shavings or zinc dust, on which the precious metals are precipitated at the expense of the zinc.

The solutions after having been brought to their original strength by the addition of fresh sodium cyanide, enter again in circulation by being returned to the grinding apparatus. The black precipitate obtained by the operation, consisting chiefly of gold, silver, finely divided zinc, lime, alumina and other impurities, is then washed in filterpresses, dried, melted with suitable fluxes, and finally cast into bars of about 30 kilos, which are exported The product is not of the same purity as that from the patio process, rarely being above 950 fine, but, on the other hand the extraction is above 90 per cent. of the silver and 98 per cent. of the gold, and the process requires only as many days as formerly weeks, and the cost is less than one-fourth.

A description of the mechanical details of the appliances used in the cyanide process would fill volumes and not be pertinent to the purpose of this paper. which is to draw attention to the great and beneficent change in methods since the time when Mexico obtained its independence, especially during the last 30 years, when continued peace and tranquility made it possible to devote all the available energy to the development of the industry.

It must be noted that since the introduction of cyaniding all efforts have been directed towards improvements on mechanical lines, in which certainly wonderful progress has been made. Our knowledge of its

chemistry has, however, not advanced at the same rate and is still very much as it was when McArthur-Forrest first advocated and practised the principle involved, with the important exception, however, that it was found that in the treatment of silver ores, the extremely weak solutions used on gold have hardly any effect, but have to be considerably strengthened, a fact which was not known at that time. Before this was known successful treatment of silver ores by cyanide was considered impracticable.

Various other chemicals in combination with cyanide have been proposed and tried, as they were supposed to accelerate or intensify the action, but the largest number of them have no effect, or are only of use with certain classes of ore. Mention should, however, be made of Clancy's proposal to add to the straight cyanide solution calcium cyanamide, an alkaline sulphocyanide and an alkaline iodide, and passing a low voltage current through the agitated pulp. The process has not as yet been fully tried on our Mexican ores, refractory on account of containing part of the silver in combination with manganese. If successful on these, many ores not amenable to straight cyanide treatment could be profitably worked in this manner. According to the experiments of the inventor even in ordinary ores a saving of cyanide is obtained as the solutions are regenerated at the expense of a less costly substance, and a trifling expenditure of electrical power. If the claims made for this process are substantiated by results on a working scale, new prospects for the industry will doubtless be opened.

We approach the end of our task, which was to indicate in broad lines the difference between the methods is use at the beginning of the century of independence and those now practised. Some of the manifest faults of our sketch are due to the disproportion between the space at our disposal and the great mass of material which imperatively seemed to demand consideration. This caused a constant conflict between the desire for completeness and the necessity for brevity, which perforce made the work fragmentary. We have dwelt more minutely on the early part of the period under consideration than on more recent occurrences. The knowledge of these early times is rapidly being obliterated and in none of the splendid and valuable treatises on old Mexican mining history is it presented in connected form, being generally overlaid by a wealth of statistics and detail, which to the non-technical reader is not calculated to increase clearness.

We are safe in concluding with the statement that especially during the period of peace and security of the last 30 years, the progress has been enormous and in expressing the hope and conviction that under a continuance of these conditions the industry will gain in importance at the rate justified by the large mineral wealth of the country.

---

(1) The old system of tentaduras as a guide in the p process was gradually replaced by assays of the amalgam, posed in 1875 or 1876 by Manuel Maria Contreras, M.E. art of making correct tentaduras has well nigh been among the younger generation of engineers.

(2) Many mines may at present be said to be in a stat transition from old to new methods and in others these side by side as, for instance, when electrically moved cars filled by peons carrying the ore and waste from great dista

(3) As early as 1870, the opinion that the industrial fu of the Republic depended upon the utilization of its g water power was advocated by mining and civil engineer the daily press and various pamphlets. At that time, how the long-distance transmission of electrical energy was ha sufficiently developed for practical application.

(4) In 1894 the Arthur-Forrest Company installed a able plant for the treatment of tailings in the State of So which they shifted from one point to another. This was lowed by stationary plants in Guanajuato, El Oro, Pach and other mining centres. In Pachuca the new plants foll each other rapidly. The last mill which has been reform that of Purisima Grande, where centuries ago the syste Bartolome de Medina had originated and where it was tised until very recently.

GEOLOGICAL SURVEY OF CANADA

Proposed Field Work, 1911.

[Editor's Note—The following list includes several specialists from the United States, whose names, marked with an asterisk, are familiar to most of our readers. See editorial.]

D. D. Cairnes.—International geological boundary line between Yukon River and Porcupine River. Co-operation work with the Division of Alaskan Mineral Resources of the United States Geological Survey. A section is needed to the Arctic Ocean and it can be most economically done while the boundary line parties are in the field and have trails opened up. The U. S. G. S. will look after the line from the Porcupine to the Arctic.

R. G. McConnell will continue work in the Portland Canal district and investigate the placer gold on Nace River.

G. Mallock will examine the anthracite district at the headwaters of the Skeena River.

C. H. Clapp will continue his geological investigation of Vancouver Island, with special reference to the Nanaimo sheet.

C. Camsell will examine the peridotite of Tulam in which the Survey has found diamonds, and st the new mineral district of Steamboat and others Yale, B.C.

L. Reinecke will conclude his study of the Bea dell mining district.

J. Drysdale will make a detailed geological inv gation of Franklin Camp, North Fork of the K River.

O. E. LeRoy will be engaged in reconnaissance in several districts in the Kootenay, and will mal detailed examination of the Nelson district.

S. J. Schofield will continue the geological map of East Kootenay.

*R. A. Daly will take charge of work on a geo cal section across the Canadian Pacific Railway in tish Columbia. He will commence this year about loops.

J. A. Allen will continue his work on this sec west of Ice River.

*C. D. Walcott as collaborator in geology with cial reference to the Cambrian of the Rockies

the neighbourhood of the C.P.R. about Field River.

. Leach will work on the coal basins along the Nest Railway.

Dowling will continue his investigations on basins in the vicinity of the G.T.P., Yellowhead

. Lawson, assisted by R. A. Wallace and J. D. , will revise the geology of the Lake of the nd Rainy River.

. Collins will continue the geological investi- of the country north of the Sudbury district.

ohnston will continue his work in the Lake district.

Taylor will continue his work on the surface of western Ontario.

uffer will conclude his study of the Devonian southwestern Ontario.

Foerst will study the Palæosoic rocks of Mani- sland.

ilson will continue his explorations in north- Quebec.

Neill will study the geology of the Monteregian uebec.

nsfield will make detailed studies of several ines north of the Ottawa River.

R. Harvey will continue Mr. Dresser's work in the Eastern Townships, Quebec.

. J. Goldthwait will continue his investigation of the raised beaches in Quebec and the Maritime Provinces.

P. E. Raymond will study the geology of Quebec city and environs.

G. A. Young will examine the oil gas and gypsum district near Moncton, N.B.

W. A. Bell will study the Joggins and other sections on the Bay of Fundy.

E. R. Faribault will continue his mapping of the gold-bearing rocks of Nova Scotia.

*H. Ries and J. Keele will study the clays of New Brunswick, Quebec and the Northwest provinces.

Topographical.

R. H. Chapman and K. Chipman will continue the mapping of Vancouver Island.

S. J. McLean will triangulate the Kootenay-Columbia Valley, as a preliminary for its topographic mapping.

W. H. Boyd will map the Blairmore-Colcman coal district.

A. C. Sheppard will finish the Slocan district.

W. Lawson will make a topographical map of the Moncton, N.B., area.

THE AMALGAMATION OF GOLD IN BANKET ORE

Paper read before the Chemical, Metallurgical and Mining Society of South Africa

By W. R. Dowling, M.I.M.M. (Vice-President).

Amalgamation being the most important source of old recovery on the Witwatersrand gold-field, recent evelopments and present varied opinions upon this bject make the time opportune for a general discuss on and review of the situation.

The author does not propose to discuss the manipulative details of the method of amalgamation: such knowledge is assumed, and the general features and present tendencies of the process with the influencing factors only are dealt with. The decreasing grade of the ore due to the fact that the reduction in working ists has brought into the paying zone ore formerly not payable, and the large scale of operations to-day, necessitates the simplification and reduction of plant and operations to the minimum. The enormous tonnages of ore milled make each item of equipment and operation cost a great deal in the aggregate and the fact that the interest on some particular non-essential item of expenditure does not amount to much per ton crushed is beside the mark, as in many cases the capital may not be available, or, if available, could possibly be employed more profitably otherwise.

As will be shown, the relative importance of the amalgamation recovery and the methods by which it was carried out have been considerably modified by various factors from time to time in the metallurgical history of the Witwatersrand. In the early days the main source of gold recovery was by amalgamation with a small amount of concentration and subsequent pulverization. The ore was crushed relatively fine by stamps, the screens mostly in use being 800 to 1,000 holes per square inch, and the discharge was set high to avoid fine crushing and inside amalgamation. To obtain the maximum recovery it was considered necessary to catch the gold at the earliest possible moment after its release from the ore by crushing. To this end amalgamated copper plates were set inside the mortar boxes, which were made large and roomy and recessed at the back to protect the copper plates. Mercury was fed into the box periodically, and lip and splash plates received the outflow of pulp. Following these plates was the large apron plate, the latter being the only plate in use in most mills to-day. It was usual to cut the apron plate into two or more lengths, and arrange these in steps, mercury wells being placed at each step for the purpose of mixing the pulp and recovering possible floating particles. A large proportion of gold remained in the mortar-box as amalgam on the inside plates and around the dies, and was periodically cleaned up. Some of the gold discharged through the battery screen had already been wetted by mercury, and was also in the form of amalgam, and was caught on the outside plates. At the present time amalgamation tends more and more to be performed by the passage of pulp over a single plain inclined stationary plate, and the above devices of the early millman are likely to be followed into oblivion by the mercury trap, in view of the most efficient mercury trap which the tube-mill circuit affords. Cyanide was the favourite chemical employed for dressing plates, and was liberally used. It might be mentioned in passing that in some mills, many years after the introduction of the cyanide process, cyanide was still in use. The large mortar boxes necessarily reduced the crushing capacity of the stamps, and it was due to the introduction of narrow straight-backed boxes for the purpose of increasing crushing efficiency that inside plates became impracticable. The mercury feed to the mortar boxes, however, continued much later, it being argued by the exponents of this practice that since a particle of am-

algam was larger and heavier than its enclosed gold particle, it was more readily caught. Inside amalgamation and mercury feed to the mortar boxes increased the mercury consumption, and made it impossible to obtain a reliable sample of the ore crushed.

Concentration by means of blanket strakes, buddles, Frue vanners, and other means was practised, and some amalgamable gold was recovered, as well as, no doubt, some rusty gold from the oxidized ore. Evidence of the amalgamable gold reaching the concentration plants is the amalgam recovery made on the small plates attached to the Frue vanners then running, and also on some shaking secondary plates installed at the Ferreira mine.

This had its influence on the crushing of the or amalgamation recovery, since, with a view to th duction of as little slime as possible, the tendenc to crush coarser, thus decreasing the amalgam ery, although the total recovery of the gold co of the ore was considerably improved.

When the treatment of slime was successfully duced by our past presidents, J. R. William Charles Butters, in 1894, an entirely new view treatment was rendered possible. The product slime being no longer detrimental to the subs treatment by cyanide but the reverse, the ore wa crushed finer, thus again increasing the recove amalgamation. The recovery by the latter p

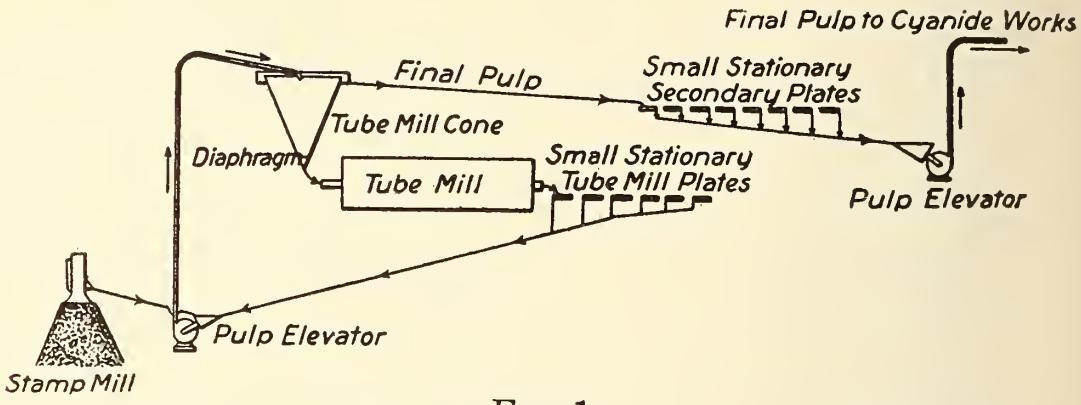

FIG. 1.

A

Information is very meagre and unreliable as to the percentage of recovery by the means outlined above. The assayer in the early days was not considered a necessary official on the mine, the pan in the hands of the mine-captain or millman being thought the more reliable means of determining the value of the ore. In December, 1894, however, J. S. Curtis sets the recovery at over 60 per cent. where a 900-mesh screen was used. It appears, then, that the percentage recovery of the early days on an oxidized and rich ore, by the various amalgamation methods then in use, was not much less than is obtained by the present fine crushing from low-grade pyritic ore by the ordinary straight mill plate and shaking tube-mill plates, as used in most reduction works to-day.

was further improved by the use of lime in th service water, used to accelerate the settlement slime, as it was found that the agglomeration particles into larger aggregates enabled these t into contact with the amalgamated surfaces an an appreciable proportion of their gold conte

The increased recovery of gold obtainable b crushing and the removal of the main objecti this procedure by improvements in sand and treatment were generally recognized before th (1899 to 1902). During this period, when lo vance was debarred, progress in fine crushin made in Australia by the introduction of tub The introduction of tube-mills for finer crush the Transvaal by J. R. Williams in 1904 raised

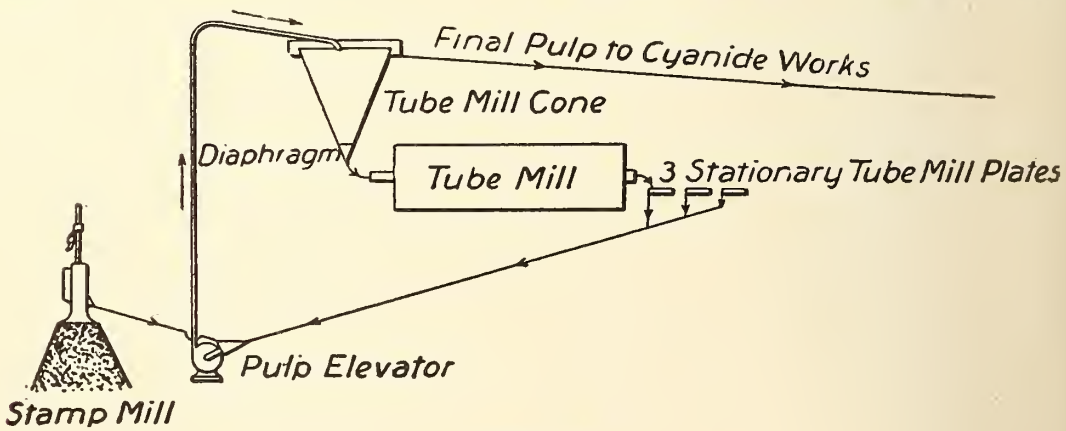

FIG. 2.

B

A most important change in the methods of gold recovery was brought about by the introduction of the cyanide process early in 1890. The cyanide process in the first instance was only applied to leachable sand.

covery of gold by amalgamation to 65-70 per c the contents of the ore, of which some 10 to cent. was by means of the tube-mill plates. The gamation recovery varied somewhat on di

ccording to the re-crushing plant erected, g used, tonnage crushed, and value and nature re.

ng nearer to the present time, it is found that eased use of tube-mills for re-crushing enables e a screen to be used in the stamp-mill that nation of battery pulp becomes an impossi- wing to the scouring action of the coarse pulp e mill plates. This necessarily leads to the of the plates from the stamp-mill in such nd a consideration of the following possible ives represented graphically in the correspond- rams:—

(A) Amalgamation of the tube mill pulp by one set s, and the overflow final pulp by another set, as Randfontein Central and Knight Central.

till crushed or abraded fine enough to overflow the classifiers.

With efficient tube-mill classification, all but the finest gold released by the stamps is brought into the tube-mill circuit and recovered on the plates, together with that released by crushing in the tube-mills. This being the case, the problem narrows itself down to determining whether it is necessary or advisable to amalgamate the final pulp, leaving the crushing plant as an overflow of the tube-mill classifiers. The considerations which enter into this problem are the extra capital outlay and buildings, the capital locked up as amalgam as setting to the plates, the increased area of amalgamated surface to guard, the consumption of mercury, the labour of dressing, and the additional elevation of pulp necessitated by

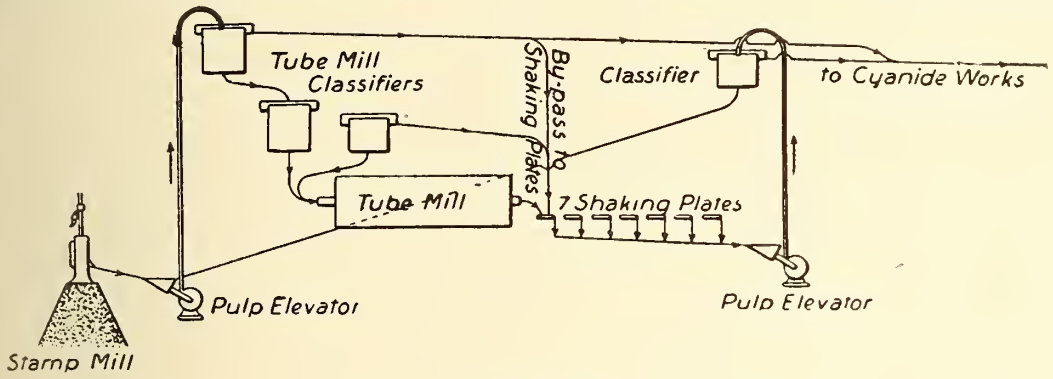

FIG. 3.

C

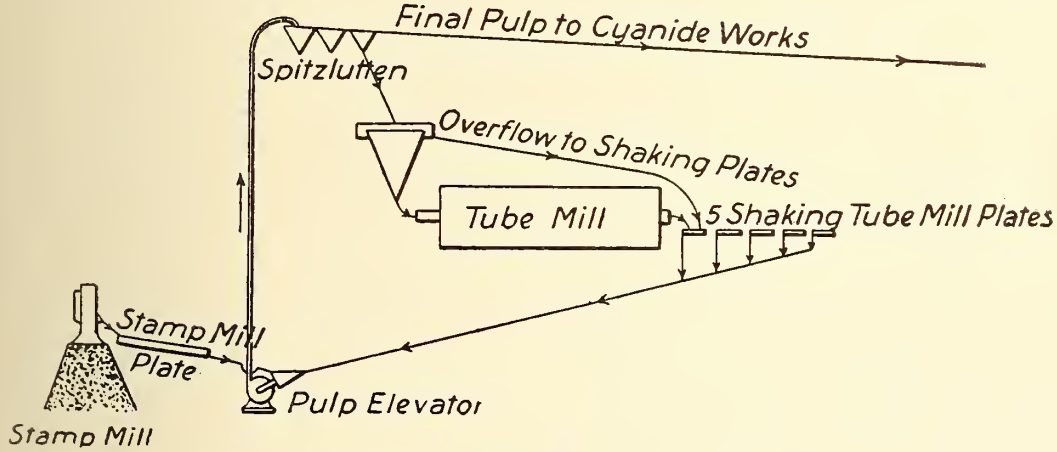

FIG. 4.

D

(B) Amalgamation of the tube-mill pulp only, as Simmer and Jack, Simmer Deep-Jupiter, and ious South Randfontein mills.

(C) Amalgamation of the mixed pulp after re- g of the coarse portion by tube-mills, as at re- erected plants.

the failure of varions efforts to eliminate tube- ates, it may now be accepted that there is gen- agreement amongst metallurgists as to the ad- sability of amalgamating the tube-mill pulp, since se considerable concentration of coarse gold by ssification of both stamp and tube-mill pulp place in the tube-mill circuit. Tube-mill pulp only to be examined for metallic iron from the f shoes and dies and from other sources to il- how heavy particles will persist in the circuit its fall during this amalgamation process. Even if mercury traps are used at the foot of amalgamated plates outside the tube-mill circuit for the pulp overflowing the tube-mill classifiers, it is possible for fairly coarse mercury and amalgam to escape to the cyanide plant.

On reference to the sketches, it will be noted that alternatives (A) and (C) have two elevations of the total pulp, plus the tube-mill pulp, whereas (B) has only one elevation of the total pulp, plus the tube-mill pulp. Alternative (B) therefore does not involve any extra charge for re-elevation, and remains the same as in the usual present-day practice, as represented in sketch (D). Unless increased recovery counterbalances these disadvantages, it is preferable to omit this additional operation. The use of very coarse

battery screening naturally reduces the amount of metallic gold set free in the stamp-mill, and where the bulk of the crushing is done by the tube mills, the quantity of very fine gold which might reach and overflow the tube-mill cones is correspondingly reduced, as such gold is retained on the tube-mill plates before the elevation of the tube-mill pulp. Even where the coarseness of crushing in the stamp-mill does not preclude the use of plates there, their elimination, when conditions permit, is followed by the various advantages above mentioned, and the rendering available as immediate profit the gold on such plates, which would otherwise not be realized until the end of the life of the mine. Plates thus taken out of the stamp-mill may carry from £50 to £300 worth of gold per plate, according to their condition, and in the aggregate this may render some £20,000 worth of gold immediately available in the case of a large mill. The elimination of the final pulp plates, however, can only be considered safe where good tube-mill classification obtains, and an equally efficient cyanide treatment follows. In the cyanide plant clean separation of sand from slime is essential, such as is possible with large diaphragm cones and continuous sand collection, producing on the one hand freely leachable sand, and on the other a large percentage of slime free from coarse

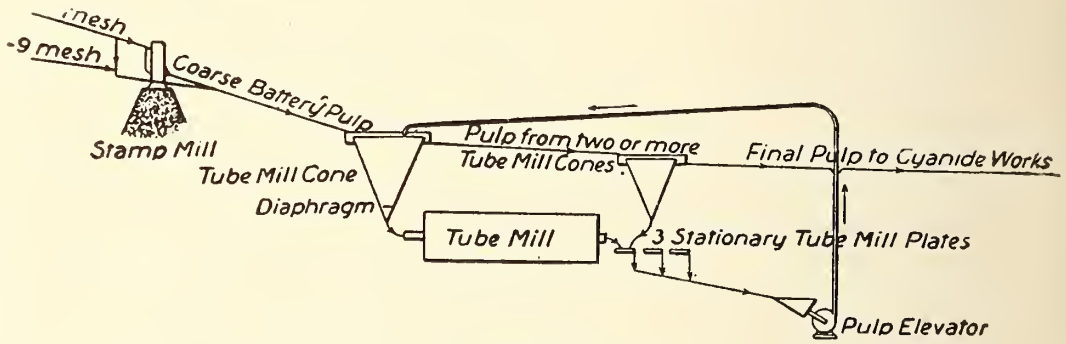

FIG. 5.

sand. With tube-mill classifiers liable to choking of small underflow outlets and consequent overflow of coarse sand and gold to the cyanide plant, and with slimy semi-permeable sand charges, the wisdom of allowing any fine amalgamable gold to escape from the crushing plant is doubtful, in spite of the economies above mentioned. In the case of the Simmer and Jack mill, where there are plates in the tube-mill circuit only, though the cyanide residues remain normal, the amalgam recovery dropped from 64 per cent. to 55 per cent. on a 6¾dwt. ore, owing to the fact that the fine sand and slime overflowing the classifiers are not amalgamated at all. If necessary, and as shown later in the case of the Simmer Deep plant, finer crushing and larger relative tube-mill cone area could be employed to increase the percentage of gold recovery by amalgamation. Whilst the collected sand is slightly enriched by some very fine free gold, there is no difficulty in dissolving this and obtaining a complete recovery. The popular theory that only 85 per cent. of this gold is recovered by cyaniding, instead of 100 per cent. by amalgamation, has not so far been borne out either in the laboratory by residue assays or regular panning of residues. Any fine metallic gold overflowing the tube-mill cones is necessarily smaller and more easily dissolved than the average of partly-encased particles in sand which are dissolved by cyanide. The amount of fine metallic gold overflowi tube-mill cones is much affected by the numbe area of the latter. Where a large ratio of tub to stamps exists, much gold, more often than no not be detected in the final pulp by panning or sand before treatment. This is the case at the mer Deep plant, where, before the removal stamp-mill plates, the total plates in operation bered 82, equivalent to 5,276 square feet, of a mating area, and the amalgamation recovery wa per cent. of the ore value. After the removal the stamp-mill plates and the reduction of those tube-mill circuit to 30 stationary plates, present area of 1,700 square feet, the amalgamation re was 57.7 per cent., and the value of sand and before and after treatment has not increased. total extraction by amalgamation and cyanidin 93.4 per cent. before and 93.5 per cent. after re of the stamp-mill plates. There was slightly crushing of the ore in the latter case, there bein per cent. of -90-mesh (0.006 in.) product in th pulp before removal of the mill plates, and 81 cent. of -90 mesh (0.006 in.) product after the re Where the ratio is lower, as at the Simmer and a trace of very fine gold can be detected by p the final pulp and collected sand, though the value of the sand residue remains normal. The is also enriched, though this may be offset by washing, due to the lower percentage of moist settlement of well-classified slime, containing a percentage of fine (-200 mesh) sand. For in assuming that 1.5 dwt and 1.8 dwt, slimes are t settling to 42.5 and 35 per cent. moisture respec by two 4:1 washes in both cases, of which th wash only is precipitated down to 0.01 dwt. p of solution. With 0.08 dwt. undissolved gold first residue and 0.10 dwt. in the second, the to traction will be 90.4 per cent. (0.144 dwt. tota due) from the 1.5 dwt. slime, and 92.2 per cent dwt. total residue) from the 1.8 dwt. slime. Butters' or other vacuum filters are used, the of the original slime should be immaterial, as viding the dissolving of the gold is satisfactor residue should contain little more than the amount encased. It is to be hoped that detail sults and working costs of the recent work i direction at the Crown mines will before long l before our society.

The author is indebted to F. A. G. Maxw much information on regular work at the Ra tein mines, where plates are eliminated from the mill, and hopes that he will bring forward his as a discussion to this paper. In the meantime,

aid that during 1908, in the four 100-stamp sec-
s of the South Randfontein, when there were am-
gmated plates both in the stamp-mill and the tube-
mi circuit, the average amalgamation recovery was
4.6 per cent., and the total recovery 92.06 per cent.,
wh eas in 1910, when there were plates in the tube-
mi circuit only, the amalgamation recovery was 48.60
per cent. and the total recovery 92.94 per cent.

s mentioned in a note lately presented by the au-
tho to this society, it has generally been considered
nec ssary for the satisfactory amalgamation of the
lar e volumes of thick tube-mill pulp that the plates
sho ld shake. Tracing back the history of this belief
to e pioneer work done by J. R. Williams on the Glen
Dee in 1904, it seems that in order to prevent the
bak ing of sand on the stationary plates installed with
10 er cent. grade, it was found necessary to mount
the plates on shaking vanner frames. Not only has
the shake been subsequently adopted by all the mines
wi out question, but the number of plates has gradu-
all increased from the two originally installed to five
and even six later. When the Knights Deep had five
tu -mills, equivalent in cubic capacity of shell to 3.91
sta lard tube-mills of 22 feet x 5½ feet, sixteen shak-
ing plates 10½ feet x 4¾ feet were in operation. As
the e was no convenient space for more plates when
ano her tube-mill was erected, it was decided to make
the sixteen plates serve. The number has now been
red ced to fourteen. The ratios are:—

Fo r 3.91 tube mills 16 plates=4.09 plates per tube-
mi

Fo r 4.91 tube-mills 16 plates=3.26 plates per tube-
mi

Fo r 4.91 tube-mills 14 plates=2.55 plates per tube-
mi

Th amalgamation recovery was just as efficient with
the smaller ratio as with the larger.

I the course of the experiment mentioned in my
not and after having thoroughly tested the station-
ary five plates system, initiated originally by F. A. G.
Ma well at Randfontein, it was decided on W. A.
Ca ecotts' suggestion to perform the whole amal-
gam ation of the tube-mill pulp on two stationary
pla s per tube-mill. The Simmer East plant has
thr 22 feet x 5½ feet tube-mills. The pulp of each
mil has been regularly run over two plates only since
De mber 19th, 1910. The dressings have been at six
hou intervals and the scrape taken six inches lower
tha formerly. The daily scrapes have been normal,
yie ing the amalgam called for. The two plates of
one of the mills were steamed at the beginning of the
run and again at the end of a month's run to deter-
min whether the yield from this source was affected
in ny way. The previous practice in this plant was
to eam one-third of the total plates each month so
tha each plate ran for three months before steaming.
It as found that one month's run of the two plates
yie ed more amalgam when multiplied by three, than
the average of the three months of five shaking plates
pre ious to starting the non-shaking experiments.
Ho ever, to be on the safe side, it was assumed that
the plates would not accumulate steam amalgam at the
sam rate during the second and third months, and it
was decided to multiply by only two and a half. This
cal lation gave a figure for steam amalgam just about
equ l to the average of the three months of five shak-
ing plates. Adding this to the daily scrape and other
sou ces the recovery is fairly arrived at, and works
out at 21.54 per cent. of the screen value and 34.17
per cent. of the tailing value, compared with 21.80
per cent. and 34.04 per cent. of the previous five-shak-
ing-plate period.

To ensure successful and economical work the ratio of water to solid should be reduced to the minimum, as not only does this decrease the velocity of the stream over the plate, but the cost for re-elevation is also less. The volume of pulp of 400 tons of sand per tube-mill plus 480 tons of water, allows about 10,000 cubic feet of pulp per 24 hours for each of the two plates, or about the same as passes over the plate of a five-stamp battery with a 9-ton duty per stamp, and a 6.5 to 1 ratio of water to ore in the screen pulp. The tube-mill circuit is the only part of the crushing plant where a thick amalgamable pulp is available without the installation and operation of special classifiers for the purpose. Distribution of the stream across the full width of the plate is also of considerable importance, and may be obtained by using the usual box at the head of the plate perforated with about ¾-inch holes along the bottom of the side facing down the plate. These holes should be of such capacity that the pulp attains some head in the box. In the event of any of the holes becoming temporarily choked, a further row of holes an inch or two higher up the front side of the box will serve to carry over the stream, and still maintain a fairly good distribution. The fall given to the stationary plates is 18 per cent. This is the fall arrived at by Mr. Maxwell and since adopted here. With the fall of 18 per cent. it is found that the minimum percentage of water in the sand is 55 per cent., and it appears that should it be desired to reduce the fall, the moisture would have to be increased, fall and water ratio being convertible terms within limits. The point to be reached in water ratio and fall is that just short of banking of the sand on the plate. Even with a low water ratio the rush of pulp over two plates appears to the eye to be too great, but this is not really so. As long as the velocity of the pulp stream is such that particles in suspension may come into contact with the plate and not be carried on mechanically without touching the plate, the gold will be caught. It might be considered that pulp carrying only 55 per cent. of moisture is too thick to allow the gold to sink through and reach the plate. As, however, amalgamation has been proved efficient with this ratio, this does not appear to be the case. In this connection, it might be mentioned that in pan amalgamation the pulp is kept very thick, although in plate amalgamation a fluid pulp was heretofore considered necessary for good recovery. On a stationary plate there appears a tendency for the gold to amalgamate further down the plate than when shaking; there is hence a liability for the scraping to yield less amalgam and the steaming more with stationary plates as compared with shaking plates. In connection with the satisfactory results obtained in the operation of the two stationary plate method, much credit is due to the practical skill and progressive attitude of Mr. A. J. Herald, the Knights Deep mill foreman, and to his assistant, Mr. Peter Wilson.

The removal of plates from the stamp-mill has had the good result of introducing on these fields the separate plate-house. The Homestake mine and the Waihi set the example many years ago, but the Witwatersrand has been very slow in following the lead and accepting the suggestion made before this society in 1903 by H. R. S. Wilkes. The arguments advanced by some millmen that a plate attached to each battery makes for good recovery due to better distribution of the pulp by the stamps over the width of the plate,

and that even vibration assists lack confirmation. It appears to the writer that this method is just one of the many practices taken over from other countries without investigation. Tube-mill plates have now been running long enough to prove that most efficient amalgamation can be performed with a pulp sub-divided from a launder and distributed over the width of the plate from a box pierced with holes. Tube-mill pulp carries heavier particles and contains less water than mill pulp, and is therefore a more difficult pulp to distribute. The advantages of a separate plate-house are increased running time, since stamps need not be stopped for plate dressing, and greater attention to the crushing machinery by the attendants, thus increasing the crushing capacity. Again, better amalgamation should be obtained by the greater attention to the work by specially chosen and trained men. The whole operation is confined to a smaller area and lends itself by closer supervision so that the risk of loss by pilfering may be reduced to a minimum. In connection with the matter of conveying pulp the author considers that sufficient importance is not attached to launders. All launders should be as smooth as possible and free from obstruction at the joints. Of all material used for the lining of launders there does not seem to be anything better than cement. This provides an ideal surface presenting least resistanee to the flow of the pulp and affording very little lodgment for amalgam and still less for gold in unamalgamated pulp. On those mines here where separate plate-houses or combined plate and cyanide extractor houses have been built, the arrangements have not gone far enough or else too far. The erection of zinc-lathes, elevator pumps and tube mills in the same building as the plates and the extractor boxes means the introduction of gangs of men and natives for repairs, other than those engaged on the gold recovery work. If this machinery is placed in the same building because the launders may carry gold, then the whole tube-mill plant, including circuit launders and elevators, should be included. The best plan is to include in the building only sueh machinery as is actually connected with recovery work, so as to limit the men entering the building to those directly engaged in the work. The accumulation of amalgam in the tube-mill launders should be reduced to a minimum and the launders should be closed to protect what does collect. Prior to the introduction of tube-milling amalgam was to be found in the launders to the cyanide plant, and some found its way as coarse particles to the concentrate vats, entailing loss in the residue. Where efficient tube-mill classifiers are installed no amalgam is found to-day reaching the cyanide plant except in an impalpably fine condition, since heavy particles of amalgam pass into and are retained in the tube-mill circuit. There is always a loss of mercury in amalgamation mainly by abrasion, and where this enters the tube-mill amalgamation of the gold liberated by crushing takes place. Where this amalgam does not reach the plates it is found in the launders between the discharge of the tube-mills and the plates. Such impalpably fine mercury or amalgam as enters the cyanide plant dissolves in the same way as gold, and like dissolved lead salts, is either wholly or partially precipitated by soluble sulphides in the working solution, or later in the metallic form by zinc shavings in the boxes.

Where plates are eliminated from the stamp-mill the water ratio may be considerably reduced. The clearing of a long plate set at a fall of 9 per cent. or 10 per cent. by avoidance of any banking of sand from the pulp has been the factor determining water ratio in the past, and this requires six to se parts by weight of water to one of solid using aver battery screening. It has been found that in the sence of mill plates the ratio may be reduced to without serious ill effects provided the mill laun have sufficient grade to carry pulp of this cons ency. A coarse screen with less water will give same result in duty and grading as a finer screen more water, water and screening being convert terms within limits. The reduction of water has c siderable influence on the cost of pulp elevation an running water pumps, the reduction of weight fr 6.5 to 4.5 of water to 1 of solid being equivalent about 27 per cent. The saving in power in a la plant is material when working on the reduced ra and there is likewise a smaller load on the classif and slime collectors. There would, however, be no s ing in the consumption of water as much the sa volumes are exposed to loss by evaporation, seep in dams, and moisture in residues.

Although there is no rule for the area of amal mating plates there is no doubt that the number area of plates in common use is unnecessarily la and when these are placed in a separate plate-ho the total area may be materially redueed. The aut is of opinion that much of the amalgam found at lower end of long battery plates is largely wor down by amalgamators wishing to present a unif bright surface all over the plate. The old practice to install plates about 15 feet long x 5 feet wide battery of 5 stamps, which equals 15 square feet stamp. Where, say, one standard large tube-mill 30 stamps is erected, and assuming that the tube- is equivalent to 30 stamps, five plates of 11 feet feet would probably be erected. The combined p area is then:—

30 stamps=6 plates 15 feet x 5 feet=450 squ feet=15 square feet per stamp.

1 tube-mill=30 stamps—5 plates 11 feet x 5 fe 275 square feet=9 square feet per stamp.

Total for 60 stamps units—725 square feet= square feet per stamp unit.

At the Randfontein Central the total plates erec amount to 9.6 square feet per stamp unit but it is proposed to use only 4.8 square feet per stamp u and there is little doubt that the latter area will quite sufficient. In the Simmer and Jack re-arra ment the plate area is about 2 square feet per sta unit. With the high stamp duties of recent years same plate area is doing nearly double the work it u to do in the past, and is capable of doing a great more. Conversely, in regard to the usual 10 per c fall, where this is increased more crushed mate with smaller water ratio may be amalgamated w equally good results. H. W. McFarren in his rec interesting little book says the fall of plates va from 1½ to 3 inches per foot, and should not be than 2 inches or 2½ inches. A fall of 2 inches foot is equivalent to 16.7 per cent., and 2½ inches 20.8 per cent., whilst the average is 18.75 per c Among the advantages due to reduced area of p are reduced cost of installation and operation. especially a reduced cost of mercury, the consu tion of mercury being in proportion to the area plate. In the Simmer and Jack plant the consumpt of mercury has been reduced to one-sixth of the mer figure. Where a large area is exposed in ama mation a proportionate amount of gold is taken to set the plates, and is not available for realizat until the end of the life of the mine. The gold l

ll-set plates may be taken at 1 ounce per square f plate. A 200 stamp-mill having 40 plates 15 5 feet will thus absorb 3,000 ounces of gold £12,000. The future points to the reduction of area to the point where only the gold too coarse aniding will be caught by amalgamation. This has probably been reached in the Simmer and plant, which has now only 18 stationary plates tube-mill circuit in place of the former 64 bat- plates and 30 shaking tube-mill plates. It will ted that the Simmer East with plates in the -mill have retained two stationary plates per ill, whereas the Simmer and Jack and the Sim- eep-Jupiter joint plants without plates in the -mill have each retained three plates per tube- The additional plate in the last two cases is a re of safety to deal with the richer pulp and to not less than two plates per tube-mill in action dressing operations. Diagram (E) shows a ed arrangement of crushing and amalgamating with three stationary plates only per tube-mill and no plates in the stamp-mill, and with safety cones for the common streams of pulp overflowing the tube-mill classifiers.

The author trusts that the foregoing account of some considerations affecting the methods of gold recovery responsible for some £20,000,000 per annum, two-thirds of the Rand's total output, may be of interest to members, including those who have visited the plants where the changes described have been effected, and he trusts during the course of his reply to the discussion to furnish future comparative details of future results.

In conclusion, the author wishes to thank Mr. G. A. Chalkley, the manager of the Knights Deep, and Mr. C. D. Leslie, the superintending engineer of the Consolidated Goldfields of South Africa, for access to information of the various mines of the group, and for permission to read this paper before the Society.

COAL-DUST EXPLOSIONS

(Abstract of Miners' Circular No. 3, U. S. Bureau of Mines.)

By George S. Rice.

as after a series of great disasters that the Fed- overnment took up the inquiry into the causes h explosions and established the testing station at P tsburg, Pa., which is now part of the Bureau of Mine. The very first work was to prove to mine oper ors and miners that coal dust would explode even f no gas were mixed in the air with it. The dust was laced in a great tube 100 feet long and 6 feet in d meter, that had a cannon embedded in one end. This annon was loaded with black powder, as a drill hole ould be, tamped with clay, and discharged. In ever instance when pure dry bituminous dust was used here was a dust explosion. Each succeeding experi ent went further to show how very dangerous coal ust may be.

Fi damp carries its own warning — the "cap" in th safety lamp—but coal dust, though visible, does not tract attention unless present in large quanti- ties. Fire damp rarely spreads through wide areas in a ine, and except in notable and very exceptional cases is controllable by means of the ventilating cur- rent.

If y mischance a large body of fire damp is ignited, t e rce of the explosion is terrific, but the effect is loca ed unless dry coal dust is present, or unless (as rare happens) the explosible mixture of air and gas exte ls through a large part of the mine. But dust accu ulates everywhere in a mine that is dry, and the last from the ignition and combustion of coal dust ay traverse miles of rooms and entries and even wre structures at the entrance of the mine.

Ga (methane) commonly enters mine workings by mu ous small blowers or feeders from the coal seam, the oof, or the floor. In most mines the quantities that nter are so small that if the ventilating current is su icient and is properly controlled, the gas is dil- ted by the air and carried harmlessly away. Only some of the mines in foreign countries and a few of hos in the anthracite region of this country are sub- t o great bursts of gas into the workings. When such occur they must be met by special methods.

As will be explained later, even small quantities of dry coal dust, easily overlooked, may be responsible for an explosion in a mine that in other respects may be considered a model mine. A chain is no stronger than its weakest link. Hence a mine in which every precaution is taken except one may be subject to a fearful disaster like that of Courrieres, France, in which nearly 1,100 men lost their lives.

Only a few years ago many persons believed that coal dust would not explode unless there was some gas (methane) in the air with it, but those who have seen the tests of the past two years in the explosives gallery of the Bureau of Mines station at Pittsburg can have no doubt that a cloud of bituminous coal dust can explode when no methane or other inflammable gas is present.

Explosions in bituminous mines happen more often during late fall and winter than during late spring and summer because the mines get dry in winter. Cold air holds less moisture than warm air. The natural warmth of a mine raises the temperature of the air that enters cold in winter. As this air gets warmer it can absorb more water; it therefore dries the walls, roof, floor, and any dust present by taking up the moisture and carrying it out of the mine.

The aim of this circular is to present the facts about coal dust in brief form and simple language, with a view to explaining to all engaged in coal mining—miner and operator alike—the dangers of coal dust and the means of lessening the risk of terrible explosions.

Origin, Distribution, and Properties of Coal Dust. How Coal Dust is made at the Face.

It is almost impossible to prevent dust being made in the working places of coal mines, for most coals break to pieces easily. The dust thus formed is apt to be dry because coal seams generally carry little water.

Even if some water soaks down from above and appears in the workings, it gathers here and there in hollows, or "swamps," and, as a rule, the larger part of a mine that is not sprinkled, or made wet in some other way, is dry during fall and winter.

Dust is made at the face in undercutting the coal, either by hand or with machines. Breaking down the coal after it is undercut makes more dust. If the coal is shot down, dust is made by the shattering action of the blast. In breaking lumps with sledges or picks, and even in shovelling up the coal, some dust is made. If the coal is "shot off the solid," it is badly broken, and much fine, dangerous dust is produced.

Methods of Lessening Dust at the Face.

Since coal is easily broken the making of dust at the face can not be stopped altogether. It is clear, however, that there are several ways of lessening the amount of fine coal and dust. The coal should always be undercut or sheared. If it can not be wedged down and blasting is needed, each shot hole should be placed in the right spot and should contain only enough explosive to do the work. Care should be taken in breaking lumps.

All fine coal, cuttings, or "bug dust" should be loaded into cars and sent out of the working places before shots are fired. There are two reasons why this should be done: (1) To keep the coal dust from being ignited by a shot; (2) to prevent the fine coal and dust being blown into the gob (from which they can not be removed) and becoming dangerous there.

In Germany a method of mining coal by forcing water under high pressure into the face through drill holes has been tried recently. This method serves to saturate the coal with water, as well as to break it down, and is said to greatly lessen the amount of dry dust made at the face. Although it is best suited to long-wall mining, the method can, perhaps, be used in wide rooms in some coal seams.

How Coal Dust is Scattered Along Entries.

Coal dust is scattered along haulage roads in several ways. Many cars have open joints or loose-fitting gates, and fine coal sifts through the openings. Larger pieces of coal are shaken off the cars by jolts in running over the mine tracks or by bumps in switching and making up trips. These lumps fall on the roads and are ground to pieces.

The air passing over the cars moves very fast because the cars reduce the space through which it has to pass. Dust lying on the cars is picked up by the current and scattered along the entries; much of the dust falls to the floor, but some of the finest and lightest collects on timbers and on projections from the ribs and roof. The latter is the most dangerous kind of dust, for unless it is dampened any shock may throw clouds of it into the air, where it may be ignited by a flame or an electric arc.

Methods of Lessening Dust in Entries.

The use of tight cars without gates will keep much fine coal from dropping along roads. Such cars are used in most coal mines in Europe and also in a few mines in this country, notably in Alabama. To keep lumps from falling off, coal should not be piled higher than the sides of the cars. If the cars are tight and properly loaded much of the dust that now gathers along the haulage roads will be done away with.

A good way to keep air currents from brushing fine dust from the tops of loads is to put strong sprays of water at the entrances to partings or sidings, so that the dust will be washed into the body of the car. This method is used in some mines in Wales.

Combustion and Explosion.

When a piece of coal burns, the carbon and the o burnable substances in the coal unite with the oxy of the air to form gases and water vapor. This u is called combustion. It is accompanied by flame heat, and the resulting hot gases and vapor tend stantly to take up many times the space filled by piece of coal and the oxygen needed to burn it.

A small piece of coal burns quicker than a l piece, and if a piece of coal of some kinds is s enough it will burn in a flash. If many particl such coal are suspended in the air, as in a dust cl so that each particle has some oxygen near it, burning of one particle may fire others and the f may spread through the dust cloud in an instant this happens, the hot gases and vapor from the b ing dust cloud suddenly take up more room and outward in all directions; in other words, the mix of coal dust and air explodes.

Coal Dust in Explosions.

The fact that dry pure dust from bituminous lignite, or asphalt explodes when ignited in the ai been proved beyond doubt by the tests at Pittsb Opinions differ as to the exact way in which the f of the explosion spreads. Some persons think gases given off by the particles of dust ignite burn; others think that each bit of coal dust b completely.

Dry coal dust in air will explode whether an flammable gas is present or not; but the presence very small proportion, less than 1 per cent., of met helps greatly to start an explosion. Fire dam mixture of air and 5.5 to 11 per cent. of methane plodes with great violence when ignited. Bu though a fire-damp explosion may be violent, it is able that such an explosion never extends all thr a mine unless the flame is supported by burning dust. Certainly, the strength of most great min plosions has been derived from coal dust and not gas.

The shock to the air from an explosion travels a of the flame itself, so it has happened that m caught by an explosion have felt the shock in tim throw themselves down or into some opening b the flame swept by. This shock, or advance wav an explosion stirs up much dust, but generally a this dust is not consumed in the flame, because is not enough oxygen present. So some of the is only charred or coked, and part of this while hot or half-pasty condition sticks to the ribs and or to props and caps.

Quantity of Dust Needed to Spread an Explosi

In certain tests at the mining experiment st at Pittsburg the bituminous coal dust used w fine that it passed through a 200-mesh sieve (one 200 openings in the length of an inch), and fl easily on a strong air current. This dust spre explosion when there was only 0.32 ounce of it pended in each cubic foot of air, or 1 pound i cubic feet of air.

It can be shown that to burn completely 0.12 ou the dust used at Pittsburg will take all the oxyg a cubic foot of air; to burn a pound of it will ta the oxygen in 133 cubic feet of air.

Fine Coal and Coal Dust.

Experiments made by the Bureau of Mines in that fine dust will ignite and spread an exp more readily than coarse dust. But if the flam shock are strong, coal of certain kinds in piece enough to pass through a 20-mesh screen (one

penings to the inch) helps to spread an explosion, n though there is no finer dust mixed with it. For reason all bits of coal that pass through a 20-mesh en may be called dust, and such particles of bi- inous or lignitic coals must be considered danger- in a mine, if they are dry, abundant, and not ed with large quantities of rock or shale dust, ch does not burn.

Differences in Coal Dust.

ests at the Pittsburg station have shown that there great differences among the dusts of different s of coal. Some ignite and spread an explosion h more easily than others. For example, in none he tests by the Bureau of Mines has anthracite dust made to spread an explosion. It is possible that er some conditions anthracite dust may ignite when ended in the air, but there seems to be little dan- of this under ordinary mining conditions. More- , in the long history of the Pennsylvania anthra- mines, some of which are very gaseous, there have r been any explosions so widespread as some that e taken place in bituminous coal mines.

ituminous coal and lignite contain much larger portions of volatile matter (matter that becomes ous on heating) than anthracite, and the larger portions of volatile matter in these coals probably much to do with the greater explosibility of their s. But some semibituminous coals, like those of New River and Pocahontas fields in West Vir- a, contain a smaller proportion of volatile matter bituminous coals and yet give dusts that make use explosions when strongly heated. So it seems something besides the fineness of the dust or the position of the coal fixes the ease with which the will spread an explosion. This other feature ap- s to be the structure of the coal; that is, the way hich the coal is bound together. Experiments be- made at Pittsburg bear out this view. It is found dusts which have about the same composition do ignite with the same ease, and the resulting ex- ions do not have the same strength.

Effect of Stone Dust.

has been proved by experiments at Pittsburg and urope that if stone dust, clay, sand, or any other erial that will not burn is mixed with coal dust, eps the coal dust from igniting easily. The more e is of such material in the mixture, the more diffi- it is to set fire to the coal dust; and when the ture contains more unburnable dust than coal dust, e seems to be little or no danger of the coal dust ading an explosion. But the unburnable material t be fine and it must be well mixed with the coal to have its full effect. If the material is coarse lumps, like pieces of rock, and the dry coal dust attered around or over these lumps, or if, when e is much shale or clay dust on the floor, the pure coal dust has gathered on the ribs, timbers, or , any disturbance of the mine air may stir up gh coal dust to feed and extend an explosion.

Explosiveness of Dusts.

s already stated, experiments at Pittsburg and where have shown that a mixture of air and the or bituminous coal or lignite may be explosive, though the air contains no inflammable gas other that from the dust. The records of mine explo- confirm the results of these experiments, for e have been explosions in shallow mines in Iowa hich gas (methane) has never been found. More- , an explosion, once started in a dry, dusty mine, travel through miles of entries and headings, even when there is not a trace of inflammable gas in the mine air. It is true, however, that the presence of even a small percentage of such gas greatly increases the chance of a dust explosion.

There have been many instances of explosions of coal dust in and about coal bins when the dust was raised into the air and set on fire. Similar explosions have happened in coal-crushing rooms. During the past year (1910) there were explosions of this kind at a plant in St. Louis, Mo., and at a cement plant in Colorado. In the latter explosion nine men were burned so badly by the flaming dust that they died.

It must not be thought that coal dust is the only kind of dust that will explode when no inflammable gas is present at the moment of explosion. Dusts of other substances containing carbon will do the same thing. Among such substances are flour, starch, and sugar. Many flour mills have been blown to pieces by dust explosions. The destruction of the big flour mills at Minneapolis in 1878 is a terrible example of ruin and loss of life caused by exploding flour dust.

Causes of Coal Dust Explosions.

air may be ignited and start an explosion in a coal

The more common means by which coal dust in the mine are as follows: The flame from a shot or the accidental ignition of an explosive in the open; an explosion of a small body of fire damp; and, more rarely, an electric arc of glowing wire or even the flame of an open lamp.

Shots or Blasts.

The long flame from a shot of black powder has been the commonest cause of coal-dust explosions in mines in this country. Blown-out shots have started many, and it is a common belief that the flame of black powder must come from a blown-ont shot to start a dust explosion. This belief is not supported by the facts, for explosions have started from shots that were not blown out, nor even overcharged. It is certain, also, that if the air at the face contains even a small percentage of gas (methane), the flame from even a properly placed and charged shot of black powder may start a dust explosion. The danger is greatest when several shots in the same working place are fired at the same time. The dust made by a shot, and any gas distilled from the coal by the heat, may be set on fire by the flame of the next shot.

Dynamite is fully as dangerous as black powder. It is quicker than powder, but gives a long hot flame, and many explosions have been traced to its use. Miners have been known to put two explosives, like black powder and dynamite, in the same hole. Such a combination is more dangerous than either explosive used alone. If the quicker-burning explosive is placed at the outer end of the charge it may blow out the stemming; if it is placed at the bottom of the hole it may blow the slower explosive while still burning into the dust raised by the shot.

Danger from Tamping with Coal Dust.

The chance of a shot of some long-flame explosive like black powder or dynamite starting a dust explosion is fearfully increased if the shot is tamped with coal dust or fine coal. Sometimes miners wet the dust or machine cuttings used for stemming in the belief that they can thus keep it from being ignited. There is little ground for this belief. If the shot is blown out, its heat instantly drives off the water, and then sets fire to the cuttings. Experiments at Pittsburg have shown that if coal-dust stemming is wet it gives a flame only a little shorter than if dry. When 2.5 pounds of black powder and 2.6 pounds of coal-dust

stemming were used in a eannon the flame with dry stemming was 64 feet long and with wet stemming 50 feet long. With heavier charges the flames would probably have been longer.

Sometimes miners use pieces of eoal of nut size for stemming in the belief that they lessen the danger in this way. It is clear, however, that ramming or tamping sueh pieees will erush them, and that the shot will break the pieces still finer and perhaps ignite them.

Fire Damp.

Explosions of fire damp have ranged next to the use of long-flame explosives as a eause of dust explosions. Methane is given off more or less from nearly all eoals, although most eoal mines in the United States do not make enough methane to be ealled gaseous. A great many of them make a little methane, but so little that the return air currents earry under 0.5 per eent., a quantity too small to be deteeted with a good safety lamp. But if a mine is dry and dusty, and long-flame explosives like blaek powder are used, the presenee of a small percentage of methane greatly inereases the chanee of an extensive dust explosion. Moreover, in those mines in whieh methane eomes from the eoal seam, the pereentage in the mine air is usually larger at the working faees; and it is "at the face" that many explosions start.

If methane eomes from the floor or from the roof, it is likely to eolleet in the gob, or where there have been falls of roof, or in plaees where the air eurrents do not eireulate. In a well-ventilated mine any body of fire damp is likely to be small, and if it is ignited there is little ehanee of the explosion spreading far unless dry eoal dust is at hand. Therefore, if a mine makes any methane at all, great eare should be taken to keep down the eoal dust in all the workings.

Electric Arcs and Glowing Wires.

That an electrie are or a glowing wire eould ignite eoal dust in the air was not thought possible a few years ago, but since then several mine explosions have been laid to these eauses. Of eourse, it must take a combination of unusual conditions to start an explosion in this way, but sueh a eombination may happen now and then. All that is neeessary is to have an are from a grounding or an overeharged hot wire surrounded by a thiek eloud of inflammable dust. If a trip of ears runs away on a dusty road and breaks the trolley or feed wires, the wreeking of the trip stirs up the air and raises dust, and if this dust is easily set on fire, the forming of an are by the broken wires may start a flame. Laboratory experiments at Pittsburg have shown that a small white hot live wire ean set fire to a eloud of dust.

Many people have believed that an open flame eould not ignite floating eoal dust unless a shoek, as from a blown-out shot, aeeompanied the flame. Yet floating eoal dust has eaught fire about bins and dusty tipples. Usually there has been little damage done beeause the dust was not eonfined, but a bad explosion in the eoal-grinding room of a eement plant in New Jersey is believed to have started from the flame of an open lamp. In mines, because the space is confined in rooms and entries, there is mueh greater chanee of the burning dust eausing an explosive wave. This possibility was shown in a recent eoal-mine explosion that started near the mouth of a dusty drift. This drift was an intake, so the air eould not have eontained any gas. A trip of ears jumped the track and knocked out some timbers, thus making a dense dust eloud that was probably fired by the flame of a trip-rider's lamp. The explosion travelled a long distance into the mine a gained strength as it travelled.

An ineipient dust explosion, started by the flame an open lamp, was seen at a mine in Yorkshire, En land. The dust that ignited was raised by a passi trip of cars. The flame followed the trip some d tanee and then ran baek.

MOISTURE IN MINE AIR.

Moisture Needed to Render Coal Dust Inert.

Experiments at the Pittsburg station and the amination of eoal mines after explosions have in eated that if the eoal dust in any part of a mine is damp that every sample of it that may be gather stieks together when pressed in the hand, there is l tle or no danger of a dust explosion starting in th part of the mine. To be so damp as this, the du must hold moisture to the extent of at least one-thi its own weight. The added moisture tends to ke the dust from taking fire in two ways: (1) The mo dust must be dried before it will flame, and the dryi takes heat, so more heat or a larger flame is needed ignite wet dust than dry dust; (2) moistened du settles to the floor and paeks there or stieks to t walls and roof. In ease of a shoek to the mine air dust eloud ean form to spread a flame.

Mine Air in Summer and in Winter.

As has been stated, eoal seams are generally d Even in the wet mines water eomes in only at certa points. Sueh water may be eonsidered as more or l aeeidental, and in most mines not artificially moi ened the working plaees and roads are dry except summer time.

All mining men have notieed that in summer t intake airways of mines become moist and even w They have notieed, too, that as the summer advan this moisture ereeps in farther, until finally in m mines the dampness extends through all the workin On the other hand, they have seen that when cold weather eomes in the fall the intake airways begin dry up, and after a while the roadways that ha been damp or wet get dusty unless they are sprinkl or watered in some way.

Another faet that has been widely notieed is t relation between explosions and the time of the ye In summer the bituminous and lignite mines in t eountry are practieally free from terrible explosion these begin when eold weather eomes. The records State mine inspectors show that there is ground for l lieving that dust explosions in eoal mines have be mueh more eommon in winter than in summer. D explosions may happen in the summer onee in a whi and in distriets where the air is dry, as in the Roc Mountain eoal fields, there is nearly as much like hood of their happening in summer as in winter, unl speeial measures are taken to keep the dust in su eondition that it will not spread a flame.

Mines are drier in winter than in summer becau the outside air in winter is eolder than the mine a ean hold little water. When this eold air enters t mine it takes heat from the mine walls. As it g warmer it can hold more water, and it takes th water from the floor, roof, ribs, and dust and th dries the mine. In summer the outside air is warm than the mine and its water-holding power is hig On entering the mine the air is eooled, it can ho less moisture, and some of the moisture is left drops of water on the walls and roof, or makes t floor wet.

Relative Humidity.

hen air contains all the water in the form of vapor an hold it is said to be saturated. Water vapor not be seen, but air that is saturated with water apr can carry more water as fog or mist.

elative humidity means the quantity of water va- in the air compared with the quantity the air ld hold if saturated, and this relation is expressed a percentage. When the air at any place is sa- ted with water vapor the relative humidity is 100 cent.; when the air is half saturated the relative idity is 50 per cent.

he amount of water vapor needed to saturate air ends chiefly on temperature. Warm air can carry uch more water than cold air. Tables showing the ntity of water vapor needed to saturate air at dif- nt temperatures, called psychrometric (or dew t) tables, are given in Weather Bulletin 235, pub- d by the United States Weather Bureau, Wash- on, D.C.

Moisture Carried by Ventilating Currents.

o get an idea of the way which the change from er to summer affects mine air, assume that in er the temperature outside a mine is 0 deg. F. and relative humidity is 70 per cent. By reckoning the figures given in dew-point tables, it can be n that under these conditions each 100,000 cubic of air carries into the mine a little over half a n of water. Therefore, an intake of 100,000 cu- eet of air per minute would carry into the mine t 750 gallons of water a day. In summer, with a erature of 80 deg. F. and a relative humidity of er cent. outside the mine, a current of 100,000 cu- feet per minute would carry into the mine 13.1 ns of water per minute, or 19,000 gallons every ours—that is, 23 times as much as under the as- d winter conditions.

e average temperature of most coal mines in this try is between 55 deg. and 70 deg. F., except near ntakes. The winter temperature of a mine differs a few degrees from the summer temperature, be- the temperature of the ground changes very and the intake air takes the temperature of the s of the mine.

peculiar fact, noted by the mining engineers of ureau of Mines and by others, is that the relative dity of the main return air current of the mine rly always over 90 per cent., no matter what the ive humidity of the outside air may be. The ge relative humidity in the returns of coal s, as shown by many measurements made under irection of this bureau, is 90.5 per cent. A lower ive humidity in the returns is found in those y Mountain regions where the air outside the s is dry nearly all the time.

Prevention of Coal-Dust Explosions.

e chance of a coal-dust explosion can be much re- d by care in using explosives. It can be reduced more by using what are known as permissible ex- ves—explosives that have passed certain tests by ureau of Mines. If these explosives are always under the conditions prescribed by the bureau, is little danger of their igniting dust.

e pressure of a small or large body of methane, nflammation of which is an important cause in ing dust explosions, can be prevented by thor- ventilation. Many mine operators are satisfied y send large volumes of air into a mine. At some s more air enters than is really needed, but not enough reaches the working places to sweep the face or to keep the gob free from inflammable gas.

Leaky stoppings, overcasts, and doors are responsible for the loss of air. A bad error in most coal mines in this country is the use of a single ventilating door in places where double or triple doors would prevent part of the loss of the ventilating current.

It is evident that although the making of dust in coal mines can not be stopped, there are ways of keeping down the quantity of dust. It is also clear that although any bituminous coal or lignite mine that is dry is liable to have a dust explosion, the chances of such an explosion can be greatly lessened. To entirely prevent dust explosions is more difficult, but they can be prevented by carrying out measures to keep the dust from igniting and to keep it in such condition that it can not spread an explosion.

Methods of Keeping Coal Dust from Being Dangerous

There are two ways of keeping coal dust from being dangerous. One is to wet it; the other is to mix or cover it with rock or shale dust, clay, or sand. If the coal dust is wet enough it will not ignite; if there is enough unburnable dust mixed with it, a flame will not spread.

Applying Shale Dust.

The stone-dust treatment for coal dust has been tested at some foreign experiment stations, and is now being systematically tried at the Altofts Colliery in England. The dust, finely crushed shale, is thrown on the ribs and timbers of the passageways and scattered in a thick layer on the floor. It is renewed from time to time, whenever coal dust begins to show on top of it. In addition, quantities of the rock dust are placed on narrow boards fastened to the posts of the timber sets, or on horizontal planks over the roadways, or on easily overturned swinging shelves made of boards or canvas. The dust is distributed in this way that it may be thrown into the air in a thick cloud by the shock of an explosion and thus smother the flame. This method of using shale dust is called the "shale-dust curtain."

Many foreign experts think the application of rock or shale dust a good method to use in those mines in which the roof may be injured by wetting.

A fine example of how well rock dust may be distributed by natural means is to be seen in the northern Illinois longwall field, where the bits of shale that constantly fall from the roof and the pack walls keep the coal dust covered up. Explosions have never happened in this longwall district, though mining has been going on there for over 40 years.

The rock-dust method of making coal dust harmless promises to be of value in the Rocky Mountain coal fields where water is scarce. Certain mine operators in Colorado and New Mexico, following suggestions made by the mining engineers of the Bureau of Mines, are now experimenting with adobe dust and sand as a substitute for rock dust or wetting.

Wetting the Coal Dust.

The first-mentioned method of rendering coal dust harmless, that of moistening or wetting it, has been tested at the Pittsburg station, and used in many mines in Pennsylvania, West Virginia, and Alabama. It has proved thoroughly successful when properly carried out. A number of ways of wetting down the dust have been tried. These are by the use of water cars, hose and nozzle, fixed nozzles for sprinkling or spraying water, steam jets, and combinations of steam jets and water sprays.

Another method, the application of a salt that absorbs moisture from the air (calcium chloride), is being tried in a number of mines in West Virginia, and promises to be of value under special conditions.

Dust can be wet down and kept moist by the systematic use of any one of these methods. The great trouble at many mines, including some in which there have been dust explosions, has been that the method adopted was not thoroughly carried out.

Water Cars.

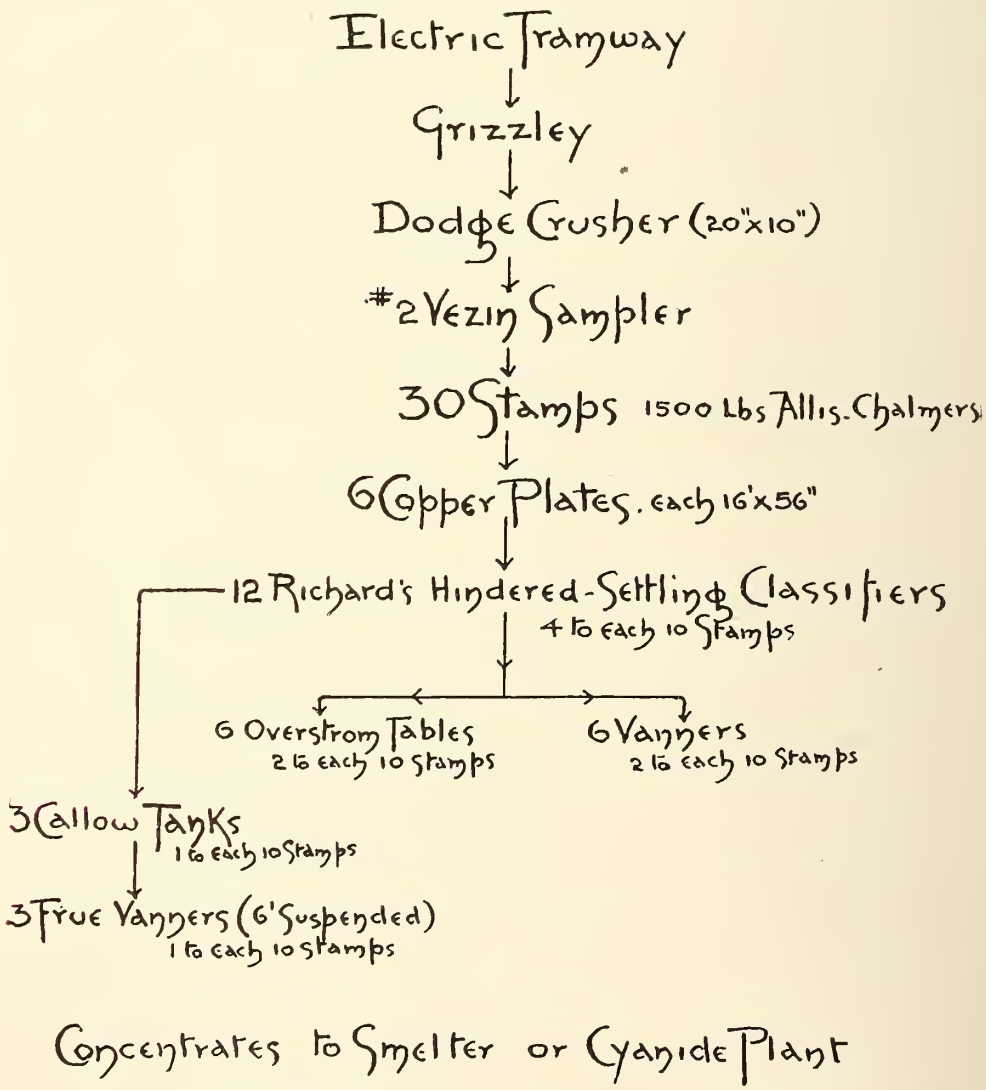
It is difficult to wet dry coal dust by throwing water on it. Perfectly dry coal dust will float a long time on water, and pouring water on such dust is like pouring water on a duck's back. Water dribbled on a dry road runs off and is lost in the loose rocks underneath the road or stands in little puddles till it drys up. For these reasons the use of water cars is not successful unless the roads are watered daily. Also, the sprinkling must be done by a force pump on the water car or by compressed air acting on the surface of the water in the car tank, so that the roof, timbers, and ribs can be wet as well as the floor. Pouring water from a bucket or dribbling it along the middle of the roadway from a valve in the tank is not a remedy and is of little value.

Hose and Nozzle.

Systematic washing down by hose and nozzle is excellent way of laying dust. The water lines shou be run along all the haulage ways up to the worki faces and should have plenty of taps for attaching hose. The washing down should be done often enou to keep the dust so damp that it will take up the n water thrown on it. To make fine dry coal dust damp that it can be molded in the hand, 33 per ce of water must be added; to make it muddy, at least per cent. must be added. The mixture would the fore contain 25 and 35 per cent. respectively, of add moisture.

The hose and nozzle method of laying dust is p ticularly suited for watering a place previous to ing a shot—a precaution that is required in so European countries. The hose may be used to sprin the ribs and roof near the track and also the gob; p vided, of course, that such sprinkling does not ca the roof to slack and fall nor the gob to take spontaneously, in which case the rock-dust met should be used.

(To be continued.)



FLOW SHEET, HOLLINGER MINING COMPANY'S MILL.

THE HOLLINGER MILL.

Before the fire at the Hollinger it was proposed to meet the whole requirements of the mill with 30 stamps. Since the fire has obliterated every trace of human activity the suggestion is to go on as be But various influences, healthy influences, are at w Therefore, it may well be believed that we shall s 100-stamp-mill at work instead of a thirty.

Personal and General

J. E. McAllister was, on May 9, at Greenwood, presented with an address by the officials and employees of the British Columbia Copper Company on the occasion of his retirement from the position of general manager of the company. Accompanying the address was a valuable service of silver, presented to Mr. and Mrs. McAllister as a souvenir of their long residence in Greenwood (since 1903) and the esteem in which they are held. The same evening the citizens of Greenwood and vicinity tendered Mr. McAllister a complimentary valedictory banquet. It is understood that Mr. McAllister intends joining a firm of consulting engineers with headquarters in New York.

Mr. John B. Hobson, well known as having for years been actively engaged in placer gold hydraulic mining on a large scale near Quesnel Forks, Cariboo district, lately returned to British Columbia after having spent several weeks in California. He will shortly proceed to Quesnel Forks to there operate his Cresta Blanca hydraulic mine.

Mr. A. J. McMillan, liquidator of the Le Roi Mining Company, recently left Rossland, B.C., on a business trip to New York.

Mr. J. L. Parker, of Vancouver, B.C., lately paid another visit to Sheep Creek, Nelson mining division, going thence to southwestern Alberta.

Mr. A. H. Gracey has returned to British Columbia from a trip to Arizona. Lately he accompanied some other mining engineers to Camborne, Lardeau district of British Columbia, to assist them in their examination of the Eva and Oyster-Criterion gold properties. For several years Mr. Gracey was manager of the Eva mine and 10-stamp mill.

Mr. C. Hussey, business manager for Messrs. Finch & Campbell, of Spokane, Washington, U.S.A., has been spending a week or two at the Standard silver-lead mine, near Silverton, Slocan, in connection with the purchase of material and plant for an aerial tramway, water system, compressor plant, and concentrating mill for the Standard mine.

Mr. Ernest Levy, of Rossland, B.C., manager of the Le Roi No. 2, Limited, has gone on a trip to England.

Mr. F. Burbidge, of the Coeur d'Alene mining district, Idaho, U.S.A., has been on a brief visit to the Slocan district, examining mining property.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay—Dominion Coal Output.

The ice conditions during the last half of April were a great hindrance to shipping, and indications were that the drift ice might give trouble throughout May. Towards the end of April, however, there was a succession of westerly winds which drove the ice down the coast, and by the beginning of May the coast was clear. Shipping commenced at the International Piers in Sydney Harbour on the 4th of May, and during the first fortnight of May the Dominion Coal Company's daily output will have averaged over 14,000 tons. The output for the month should be about 330,000 tons.

The amount of coal stored at the mines during the winter was unusually large. At the mines over 300,000 tons was banked and at the Steel works a stock of 120,000 tons was ain d n. During the past winter the mines probably worked nor gularly than they have ever done in the slack sea- on e old days of idle winters and feverish summers have d ut assed away, and the Glace Bay mines work as steadily he ye round as any bituminous collieries in operation. There re fe places where a miner can obtain steadier work the ar r nd than at Glace Bay at the present time.

The oundations are being put in for a new electric water- io tin engine to replace the present electric hoist at the n ern ional Water Shaft, which is the main drainage sta- ion fe the Harbour Seam mines. The new hoist will be fit- ed wi a Siemen's Ilgner fly-wheel equalizer, by which the tor l- energy of a rapidly revolving and heavy fly-wheel ll d to equalize the fluctuating load of the hoist. This e e s largely used in Germany and in European mines, and lso in he United States, but there is probably not one yet stalle in Canada.

The ominion Coal Company's mines are now large users f elec ic power, the current from the main transmission line ing ed to drive the screening machinery, ventilating fans, ps nd auxiliary haulages underground, and for lighting co eries. The first electrically-driven air-compressor in is pa of the country is now being erected at No. 12 Col- o far none of the coal-hoisting engines have been tri but it is more than probable that the near future will see one or more of these installed in Cape Breton. The shallow cover in the Glace Bay field affords an ideal opportunity for the transmission of electric current to underground pumps and haulages through the medium of boreholes.

Construction work has commenced on the new loading pier at Sydney, and the railway tracks are being laid. Work on the excavation of the foundations for the new wash-plant has also been started. The erection of the coal-handling plant at No. 2 Colliery will commence some time in May. The foundations are completed.

The Albion Mine Fire.

Mr. C. J. Coll's letter in your issue of May 1st demurs to references made in this correspondence on one or two occasions to the mine fire which took place at Stellarton in March, 1910, as "credit-claiming reports," and states that "there has been neither warrant nor occasion for the 'full meed of credit' given and so unctuously taken." Mr. Coll is mistaken in supposing that your correspondent or any other person in Cape Breton wishes to claim credit unduly. Reference to the correspondence will show that no attempt of this kind has been made, any more than to quote the official report of Mr. Thomas Blackwood, the Deputy Mine Inspector, as printed in the Nova Scotia Mines Report. Mr. Blackwood was one of the persons engaged in fighting this fire, and had every opportunity of forming a proper opinion of the usefulness of the rescue apparatus used, and it is Mr. Blackwood's report and not your correspondent's opinion that Mr. Coll objects to. Although he accompanied the trained men with the apparatus to Stellarton, your correspondent acting under instructions, did not go into the mine, and would not presume to give an opinion from hearsay only. No good could arise from attempting to answer Mr. Coll's letter in detail, and your correspondent can only refer your readers to the full text of Mr. Blackwood's report, at the same time disclaiming any unprofessional desire to claim undeserved credit for either the Cape Breton men or the apparatus which they used.

Mr. Coll believes that the uses of rescue apparatus or smoke helmets are strictly limited. So they are, and no person has urged this point more than your correspondent, but there are times when oxygen breathing apparatus has proved invaluable.

If Mr. Coll wishes to emphasize the folly of glorifying breathing apparatus to the exclusion of reasonable precautions, or of regarding it as a panacea for mine disasters and fires, and wishes to set forth the strictly limited uses of such apparatus, he will have the sympathy of all practical men. No multiplication of Rescue Stations or provision of modern apparatus will offset laxity or bad conditions of mining, and the use of breathing apparatus by untrained men is mere suicide. But when Mr. Coll says that the services of the Cape Breton men "were not required," many persons who know the circumstances under which these men worked in fighting the fire at the Albion mine will think that he is just a little unfair to them.

BRITISH COLUMBIA.

The spring season, which is more favourable to mining operations than the winter, is generally later in the mining districts of the Province than was expected it would be. Cold weather has retarded the melting of the snow, so that the commencement of hydraulicking in the placer-gold mining districts has been delayed two or three weeks, while in some parts where lode mining is the principal industry, hauling ore has had, of necessity, to await hardening of roads.

Much activity is noticeable in connection with newer camps, though still early for important work to be undertaken. Newspaper stories of Steamboat Mountain camp, for instance, suggest that many will go in to prospect in this new field. Again, many are preparing for an active season in the Portland Canal district, and others in country tributary to Skeena River. Development of coal lands on Graham Island, of the Queen Charlotte group, is promised; an increase in production of coal in Nicola Valley district is being prepared for; and coal mining operations in the vicinity of both Granite Creek (Tulameen) and Princeton (Similkameen) will be continued. Sheep Creek gold mines are likely to have done on them development on a larger scale than in the past, while the erection of new stamp mills, for the Mother Lode and Nugget mines, for which it has been announced that provision has been made, will enable a much larger recovery of gold to be made this year than in the past. In other parts of Nelson mining division than Sheep Creek—about Salmo, Ymir, and Nelson City, especially—the outlook is good for more mining and larger production than last year. In East Kootenay both lode and placer mining should be fairly active. Rossland and Boundary mines may be unfavourably affected by continued idleness at the Crow's Nest coal mines, if an agreement between operators and the miners' union be not soon made, and work be resumed at the several collieries, but there is still hope that some mutually acceptable understanding will be arrived at and long, protracted idleness be thereby avoided. Notwithstanding that there are some discouraging features in the situation, there is on the whole good reason to look for a continuance of operations on a scale that will result in last year's excellent record of progress being well maintained.

Slocan.—Melting snow has made wagon roads and trails too soft to allow of ore being hauled or packed to the railway or steamer shipping places, consequently few Slocan district mines shipped ore during the month of April. Similar conditions will largely prevail in May, so production will, from records of quantities of ore and concentrate received at the smeltery from the Slocan, appear to have been small. In several mines, though, development has been continued all through the winter, with generally satisfactory results. The most marked progress made has been in connection with three mines in Four-mile Creek camp, namely, the Standard, Van-Roi, and Hewitt-Lorna Doone group. Latterly further development at the Standard has been to some extent discontinued and the shipment of ore stopped, pending completion of an aerial tramway from the mine 7,900 feet down to the mill-site on Slocan Lake, immediately north of Silverton. The carrying capacity of this tramway will be about 20 tons an hour, with forty 850-pound buckets on the ropeway. Construction is being advanced, with towers in course of erection, an and steel materials arriving from the manufacturing Machinery for the Standard Silver Lead Mining Com concentrating mill is also being received; meanwhile the sary grading and log-cribbing has been done and framin timbers for the mill building got well forward. The mi have a crushing and grinding capacity of 200 tons a da for the time it will not be necessary to keep this part plant running continuously, since jigs and other concent machinery being installed are for treatment of only 10 per diem. Further, about 30 per cent. of the ore produ the Standard mine is of first-class grade and is shipped to the smeltery, while second-class ore after having crushed will be passed over a picking belt, so that all or grade suitable for smelting without previous concentratio be sorted out before the remainder shall be fed to th It is expected that the mill will be completed and in ope by October 1, while the water system for power purpose the aerial tramway, will both be in working order s weeks earlier. The Van-Roi Mining Company's mill, after delays extending over several months, caused by delivery of machinery, commenced concentration of ore March 15. During the month of April the quantity put through the mill was 3,273 dry tons, the product of was about 190 tons of silver-lead and 230 tons of silv concentrate. The former product, which averages abo per cent. lead, is shipped to Trail, B.C., and the latter, aging 44 per cent. zinc, to Bartlesville, Oklahoma, U.S.A importance of this mine is indicated by the following —during four calendar years, 1907-1910, the aggregate o roll payments made in connection with the operation Van-Roi mine and mill (heretofore the company has ated the Wakefield mill under lease) was $300,843. development work in the mine is chiefly opening on level extensions of the same shoots of ore as were worl levels above. The largest of those shoots, though n stoped out, has yielded from stopes between Nos. 4 levels approximately 60,000 tons of ore. No. 5 has a opened several shoots of ore proved in higher levels large and of a good grade. Two veins are being c known as the Main and Beryl veins, respectively. The c for the mine, in which much development work has bee and large quantities of ore blocked out, is so favourab a long and profitable run of the mill is confidently ex The Wakefield mill is to be used to concentrate ore fr Hewitt-Lorna Doone mines, owned and operated by t verton Mines, Ltd. For several years the developm these mines had been in progress until now there is mu available and easily accessible for extraction. The Wa mill plant is being overhauled, and to its equipment f duction of lead and zinc concentrates is being added Vacuum Process plant, for treating the zinc middling This mill will be running in June, and thereafter wil expected, add materially to the total of mineral pro from the Four-mile section of Slocan district. Other properties tributary to Slocan Lake that are being are the Mollie Hughes and Sweetgrass, near New I Buffalo, above Four-mile Creek; Eastmont and Enterpr Ten-mile Creek; Arlington, Ottawa, Meteor, Black Prin Hampton, on or about Springer Creek; and several ot various parts of the district.

Coast.—Reports are persistent to the effect that ore grade has been found in the Britannia mine, Howe Much development work has been done on this big p during recent years, but although large bodies of or been opened, the great bulk of the ore has been of grade that, with copper at a low price, there would ha little profit in extracting and smelting the ore. Howe velopment work has been persistently continued, and t centrating mill operated in a comparatively small wa some time the expenditure on mine and mill totalle

00 per month. Latterly the amount has not been so large, if the reports above alluded to prove well founded, a n to the earlier scale of operations will be made. Texada Isl d mines are expected to maintain production this year on a irly large scale. The Marble Bay mine has worked a sho of bornite ore, containing also good value in gold and silv, down to a depth of about 1,200 feet. The Cornell mine, in e same vicinity, is being further developed by the Tyee Co er Company, and it is expected a considerable quantity of e will be sent to the company's smeltery on Vancouver Isl d this year. Farther north, the Hidden Creek Copper Compar's mine, on Observatory Inlet, is stated to be developing mo encouragingly. Reports place the estimated quantity of ore found by underground prospecting, partly by extending the workings and partly by diamond-drilling, at a far larger total than when the property was taken under a working bond and option of purchase by the Granby Company, which, it is understood, will shortly make another payment on purchase account. Mr. James Cronin, formerly manager of the St. Eugene mine, East Kootenay, is among those returning to the Skeena district to do further exploration work on new properties situated in that part of the province. Both Portland Canal camp and Moresby Island of Queen Charlotte group, are expected to make an improved showing this year. Lode mining in Atlin district, some of which was done in 1910, will again have attention. The rich gold ore taken last year from narrow veins on the Northern Partnership group, gave such good returns that it is probable more work will be done on this property this year. Other lode claims in Atlin district will also be developed.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax, N.S., May 28.—The long and bitterly-fought strie at the Springhill coal mines was ended yesterday afternoo when the men adopted the report of the Settlement Commitee. The points of agreement under which the strike is brought to an end, as adopted at the meeting of the miners in Springhill, are as follows:—

() The men to be taken back as soon as places can be found for hem, the company saying it hopes to find employment in 45 ays for a majority of the men.

() The schedules of the mechanics are to remain, with no reductions of the rates before the strike.

() The Longley Board's fine, that is, the docking system, is t govern.

() Coal cutters are to get ten per cent. less than the rate pai before the strike, fair consideration to be allowed to enable a man to earn an average wage where changing conditions m al make that necessary. When the men went out J. R. Cowns, the former manager, announced a reduction of fifteen per ent.

() The usual clause that any employee may appeal to his employer against an alleged grievance, with an ultimate appea to President Plummer.

The Longley Board of Conciliation refused to say that the Uned Mine Workers ought to be recognized; it refused to recmmend an increase in wages or to compel the company to adt a fixed schedule as to prices.

The men rejected the report of the Longley Board, and wrk to enforce their demands for an increase in pay, and for he removal of what they said were grievances. They now ret n without the removal of any of the grievances, without recgnition of the United Mine Workers, and at ten per cent. less wages for coal cutting.

Some 1,200 men have been idle for twenty-two months, and the loss to the miners is estimated at $500,000. The strike has been costly to the United Mine Workers. It is known that whe President White did not force a settlement, his sentime and that of the present United Mine Workers' executive wa strongly in its favour. P

Sidney, N.S., May 16.—An interesting statement regarding the earnings of coal companies in Nova Scotia was made by Geeral Manager Cantley, of "Scotia," at a reception on the company's new ore carrier.

Mr. Cantley said that much was written by persons entirely ignrant of the subject as to the "fabulous returns received by Nova Scotian coal mines, but when it was realized that the "Sotia" company made a profit of less than 25 cents per ton on all the coal it mined last year, it would be seen what the foundation there was in these assertions.

The Dominion Company made a somewhat higher profit, but there were many companies in the province which earned even less than this. For the amount of the capital and the risk involved, Mr. Cantley said he considered that Nova Scotian coal mines yielded the poorest return of any industry he knew of.

ONTARIO.

Cobalt.—The sale of the Cobalt Central properties at Cobalt, which was to have taken place to-day, has been postponed until June 17.

Cobalt.—A contract has been signed whereby the low grade ore of the Crown Reserve Mining Company will be treated in the mill of the Nova Scotia Cobalt at Peterson Lake. Arrangements, including the building of a long aerial tramway, will be commenced at once, and there will be no more time lost in making the bargain operative. The contract is on a flat rate per ton treated, with a certain extraction guaranteed. The bullion will be returned to the Crown Reserve for shipment.

At the Crown Reserve ready for immediate shipment is 350,000 tons of low grade on the dump, estimated by Mr. Cohen in the last annual report to be worth $250,000. This is being added to from development work very materially every day. In addition the lower levels of the Crown Reserve promise to furnish a very large percentage and tonnage of low grade ore, and either a mill of their own or a custom concentrator was urgently needed. By the new arrangements the assets in the big dump will be more quickly available than if the construction of a concentrator were attempted.

Cobalt, May 18.—The sixteenth mill to be erected in the district, that of the Cobalt Lake Mining Company, is progressing rapidly, and the management hopes to see the stamps dropping in August.

The first drills were set up to make the excavations on March 27: to-day all the foundations are in, and half of the framing has been done. The whole of the plant is either on the ground or in transit. The mill will be of 20 stamps, and will embody most of the features used in connection with water concentration in the Cobalt camp. A very large percentage of the extraction is expected to be made on the six jigs above the stamps.

Elk Lake.—A five-stamp mill, a compressor and a couple of boilers are now being installed at the Thelma Gold Mines, in Bryce Township, midway between Elk Lake and Earlton, on the T. & N. O. Dr. Bell, of McGill University, is now on the property, making examination. Montreal and French capital is largely interested in the enterprise.

Gowganda.—It is announced from Gowganda that both the Millerett and the Miller Lake-O'Brien will make several ship-

ments from the camp this summer in spite of the deplorable condition of the waggon road.

BRITISH COLUMBIA.

Nelson, May 16.—The Windermere Mining, Milling and Development Company, with offices at Moyie, has been incorporated for the purpose of pushing development work on the Estella property, under bond to them, and all other mineralized claims from the base of the mountain to the Estella mine.

Nelson.—Ymir is situated 18 miles south of the city of Nelson, and about seven and a half miles north of Salmo, the Sheep Creek distributing point, on the Salmon River, in the very heart of a great mining district which contains nearly all, if not all, the precious metals sought after. Wild Horse, Bear, Porcupine and Hidden Creeks flow from an easterly direction and empty into the Salmon at or quite close to the town of Ymir. These creeks range from 10 to 17 miles in length, with abundance of timber, and numerous branches. It is over these creeks the now famous Sheep Creek gold belt extends, and beyond the question of a doubt by those familiar with the various ores and formations of the district these same gold producers of to-day, now found on Sheep Creek, will within the next year or two be found on or quite near the summits of the creeks just mentioned, which the quartzite belt, with its mammoth quartz and other dykes, traverses, and which in another month will be free from snow and available for prospecting. It is quite possible some strikes will be made this summer, for rich ores used to be brought to town from the heads of these creeks in the early days, to which no attention was paid owing to the narrowness of the veins. In future more attention will be given these, as on Sheep Cr These, with the veins already discovered in the vicinity in the district at large, will sooner or later be made kn abroad, the result of which can only be surmised.

YUKON.

Dawson, May 13.—The Yukon will be open for the seas navigation next Thursday, when a flotilla of six steamers eight barges will start from Lake Lebarge for Dawson, F banks and Iditarod, carrying 800 tons of freight.

Every steamer will be crowded with passengers rushin the various camps, largely on the lower Yukon.

Many now at White Horse will walk across Lake Leb on the ice to catch the steamers.

The American boundary survey expedition, comprising men and 150 horses, will catch the steamer Canadian at Yu Crossing next week, come to Dawson, and transfer here to steamer St. Michael, which will take them to the mouth of Porcupine River, where they will transfer to the steamer I for Rampart House.

The first steamer from Dawson for Iditarod will sail May It will be the packet Sarah. The Sarah will return imm ately from Dikeman, bringing the first Iditarod gold and sengers this year for Seattle. It is due here on the re trip June 5.

The first steamer from Fairbanks this year will be Schwarks, expected about the 24th.

A fleet of small boats with passengers for Dawson has pa Big Salmon.

The mails are now moving in canoes and launches.

MINING NEWS OF THE WORLD.

GERMANY.

Germany is endeavouring by every means at her command to create an oversea market for her coals. Germany is the only country on the Continent of Europe which can, and does, raise more coal than is required for her inland consumption. Charters for carrying German coal to French, Italian, Egyptian and even South American ports were at one time of rare occurrence; now they are almost familiar. German coal agents, backed by scientifically organized efforts, have succeeded in forcing coal into markets at one time held exclusively by British coal exporters. What she is doing can be best illustrated by the statement that no fewer than 58 vessels cleared from Rotterdam last month with cargoes of German coal for Mediterranean and other ports. A notable increase in Germany's coal export trade will undoubtedly be shown this year when the statistics are available. The labour disturbances in British coalfields have been a powerful factor in favour of Germany's efforts to find markets for her surplus coals.

GREAT BRITAIN.

At the House of Commons, May 1st, Mr. Masterman, M.P., Under-Secretary for Home Affairs, received a deputation from various societies of colliery examiners for the discussion of provisions in the Coal Mines Bill affecting the duties and status of firemen and deputies.

Among other matters the deputation asked that firemen and deputies should have an opportunity of appealing to some tribunal in cases of arbitrary dismissal; that the eyesight test should be of a practical character; that men now satisfactorily performing the work should not be prejudiced by the introduction of the examination system, and that in the provision that firemen and deputies should, where practicable, devote their whole time to those duties, the qualifying words "where practicable" should be struck out.

On this last point, Mr. Masterman asked if the adoption of the suggestion would not destroy the whole deputy syste it now existed in Northumberland.

Mr. Coulthead: That is so.

Mr. Masterman: The words "where practicable" were i duced to meet the case of Northumberland.

Mr. Williams and other members of the deputation conte against combining the duties with extraneous work.

Mr. Masterman said that if the amendment suggested made they would have to rearrange the mines in Northu land, and many deputies might be displaced. He sugg that the point was met by the provision that districts sh not be too large. If there were other duties to perform districts must be smaller accordingly. He promised, how that the various suggestions made should be carefully sidered.

SOUTH AFRICA.

Johannesburg.—At the end of December the reef-bearing of the East Rand Proprietary was 3,417 claims, of which or 7.8 per cent., had been exhausted. The company has mitted its calculations as to minerals underlying townships bewaarplaatsen in the vicinity of its claims, but up t present no notification has been received from the Union ernment in connection with the matter. The total profi the year figured at £1,269,935, out of which two dividen 20 per cent. were paid amounting to £962,358. Profits ta sorbed £108,930, and the sum of £160,553 was appropriate the redemption of capital expenditure. The total of the ter came to £864,932, the principal items being:—

Excess development and shaft-sinking	£43
Machinery, plant, building	31
Reduction plant	10

There were crushed 2,126,334 tons during the year of an age assay value of 7 dwts. per ton, yielding 691,860 o equal to 6.5 dwts per ton. The value was £2,900,883, o

per ton, while the cost of production was £1,651,527, or verage of 15s. 6.4d. per ton. The rate of profit was 11s. er ton. Compared with the previous year there was an in- e of 1d. per ton in working cost. This contrasts with a f 2s.2d. shown by the other great Rand consolidation, the n Mines.

e ore reserves increased by 1¾ million tons, the payable gegate being 10,274,000 tons, which is below the figure mplated by Sir George Farrar in his speech of a year ago. ng payable and unpayable ore together, the reserves in- ed by 2,578,516 tons. It is thus evident that the propor- of payable ore has diminished, the value of the entire tity has dropped 1s. 3d. per ton. It is, of course, the pay- ore that is the true criterion. The footage driven, risen sunk was 110.084 feet. In this important particular the Rand Proprietary leaves its rival, the Crown Mines, very hind, the total of the Eckstein amalgamation being 58,750

Whereas the Crown Mines opened up 2,366,000 tons, the Rand exposd just over six million tons. It is worth no- g that the Crown Mines' reserves are just 1 dwt. higher those of the Farrar organization, but this margin is likely lesseued as the proportion of reserve in the western part e Crown Mines is reduced. The actual value will be tem- rily affected by development done in the water rights sec- of the Crown, exploited by arrangement with the Govern- . In the East Rand the total development is about 121

hannesburg—The gold output for April of the mines on Witwatersrand amounted to 638,421 ounces of fine gold, from the outside districts 29,293 fine ounces, total 667,714 es, valued at £2,836,267, as against 676,065 ounces, valued 2,871,740 in March. This is a decrease of 8,351 ounces, or 73, on the month. The daily average for April was 22,257 ounces, against 21,809 ounces for the previous month, and breaks the record of 21,815 ounces created last February.

UNITED STATES.

Bisbee, Ariz., May 15.—The much-talked-of merger of the Calumet & Arizona and the Superior & Pittsburg has at last been formally made, and hereafter these two great Bisbee properties will be one.

Miami, Ariz., May 17.—During April the Old Dominion of Globe concentrated 11,085 tons of ore, smelted 29,275 tons of charge (ore, flux, etc., mixed), and produced 2,515,000 pounds of copper.

Spokane, Wash, May 10.—Nine dividend-paying mines in Shoshone county, Idaho, in the heart of the Cœur d'Alene district, earned net profits amounting to $2,500,000 in 1910, or $500,000 more than in 1909, according to a statement compiled from official reports by John Dolan, county assessor, who also says that more than $5,000,000 was paid by the operating companies for extracting the ore, the major portion being for labour.

The gross earnings of the Bunker Hill & Sullivan mine, heading the list, amounted to $3,514,431, the Federal company's properties at Mace and Wardner each being near the $2,000,000 mark.

The chief dividend payers are the Bunker Hill & Sullivan, the Federal Company's properties at Wardner and Mace, the Hercules and the Hecla. The new producers are the Caledonia, with net profits of $165,597, the Stewart with $21,788, and the Success with $10,049. Bunker Hill and Sullivan heads the list with $971,263, or about $400,000 more than in 1909. The Hecla's profits are placed at $216,909; the Federal's Wardner property earned a net profit of $285,303, while the Mace property shows a gain of $493,439, as compared with 1909. The Morning mine, also owned by the Federal Company, lost $40,000, though it handled 333,900 tons of ore.

COMPANY NOTES

DOMINION STEEL-COAL COMPANY.

Abstract of President Plummer's Report.

ur directors have filled the vacancies caused on the board e Steel Corporation by the appointment as directors of the Horable R. Dandurand and of Sir William Mackenzie of Toronto.

al Earnings—In considering the statement of earnings you directors would remind you that the period covered by the report includes four months in which the strike existed, that even when ended it was many months before the disor- ganization which it caused ceased to be felt, and that an extra winter period—December, 1910, to March, 1911—is included, during which earnings are necessarily small. The net result, under these conditions, is in your directors' opinion reason- ably satisfactory.

e Coal Company's plant is in very good condition, and you directors look for an increased production in the current financial year.

Dominion Iron & Steel Company.

siness of the year.—The expectations of your directors that the new coke ovens would be ready last autumn were not fulfilled, and the additions to the plant generally have been much delayed by various causes, among them difficulty in ob- taining suitable labour. For the ten months just closed we have, therefore, only maintained the proportionate output of the previous year, the figures are as follows:

	Tons.
Pig iron	205,865
Steel ingots	250,462
Rails	109,534
Wire rods	68,602
Billets and blooms sold	28,040

In the new year beginning 1st April, 1911, the plant now in operation should produce 290,000 tons of pig iron, an increase of about 50,000 tons, with a corresponding increase in finished products.

The bounties on pig iron and steel ingots received during the year were $316,045.21, being $228,365.97 less than in the previous twelve months, and they ceased altogether on 31st December last. The bounty on wire rods for the ten months amounted to $459,817.50.

Property Extensions:—To increase the annual production of your plant, to which we must look for such a reduction of costs and increase in earnings as will compensate us for the lapsing of the bounties, and to meet the demands of our customers, your directors have authorized the erection of another blast furnace, which will make six in all. The erections will be gone on with as soon as possible.

The new work on hand at the date of our last meeting, or since arranged for, which should all be completed within 18 months, will increase the capacity of the plant from 250,000 tons per annum of finished steel to over 400,000 tons, and your directors have no reason to doubt that the effect of this increase in the lessening of costs and the enlargement of earnings will be satisfactory to the shareholders.

The Bounties.

Bounty on Wire Rods.—Under the proposed reciprocity trade agreement with the United States, wire rods will enter free into both countries, and the confident expectation of your directors that on the lapse of the bounty on wire rods a duty

would be imposed has therefore become impossible of fulfilment. Application was at once made to the Government for an extension of the bounty for a term, during which preparation could be made to market in other forms the material now sold as wire rods, but no reply has yet been given.

While they would not minimize the loss which the company must suffer if the bounty is not extended, your directors have every confidence that the effect will be ultimately overcome when the plant is completed.

Vacancies on the Board.

Vacancies on the board.—Your directors filled the vacancies on the board caused by the death of the Hon. L. J. Forget and Mr. H. F. Dimock, by the appointment thereto of Mr. E. R. Wood, of Toronto, and Mr. Mark Workman, of Montreal. At the annual meeting you will be asked to elect, in addition, the Hon. R. Dandurand, of Montreal, and Sir William Mackenzie, of Toronto, who have joined the board of the Dominion Steel Corporation, Limited.

LA ROSE IN APRIL.

During the month of April La Rose produced 289,895 ounces of silver of gross value of $155,548. Net profit for the month was $101,325, as compared with $95,878 after March.

For the first four months of the current year La Rose produced 1,200,931 ounces of silver of gross value of $630,386, and net of $424,279. This is at the rate of $1,275,000 per annum, or more than twice the amount required for the pre 8 per cent., or 40 cents per share dividends on the 1,49 shares outstanding.

STEEL OFFICIALS.

The officials of the Dominion Steel Corporation have elected as follows for the ensuing year:

Steel Corporation.

Mr. J. H. Plummer, president; Sir Wm. C. Van Horne, president; Mr. C. S. Cameron, secretary and treasurer; Mr A. Doig, assistant secretary and assistant treasurer; Exec Committee—The President, the Vice-President, Mr. Wm. Master, Mr. J. R. Wilson, Sir Henry M. Pellatt, Mr. Fre Nicholls.

Dominion Coal Company.

Mr. J. H. Plummer, president; Mr. J. R. Wilson, vice-p dent; Mr. C. S. Cameron, secretary and treasurer; Mr. W Doig, assistant secretary and assistant treasurer; Exec Committee—The President, the Vice-President, Sir Wm. Horne, Mr. Wm. McMaster, Hon. Robert Mackay, Mr. J Wanklyn.

Dominion Iron & Steel Company.

Mr. J. H. Plummer, president; Mr. Wm. McMaster, President; Mr. C. S. Cameron, secretary and treasurer; Mr A. Doig, assistant secretary and assistant treasurer; Exec Committee—The President, the Vice-President, Hon. R Mackay, Sir Wm. Van Horne, Mr. J. R. Wilson, Mr. Caverhill.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Shipments from the Cobalt camp for the week ending May 12, in pounds:

Nipissing	130,380
La Rose	59,530
Temiskaming	58,760
Hudson Bay	64,360
McKinley-Darragh	62,340
Right of Way	60,200
Buffalo	54,850
Coniagas	64,710
Kerr Lake	60,034
Total	615,164

Following are the shipments from the Cobalt camp for the week ending May 19, and those from Jan. 1, 1911, to date:

	May 19. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	62,615	657,858
Buffalo	.....	1,061,830
Chambers-Ferland	62,900	511,800
City of Cobalt	.....	427,780
Cobalt Lake	61,420	1,749,270
Cobalt Townsite	.....	351,840
Colonial	.....	42,000
Coniagas	61,000	1,651,890
Crown Reserve	.....	946,960
Hargraves	.....	41,100
Hudson Bay	.....	310,480
Kerr Lake	60,082	1,141,980
King Edward	.....	40,000
La Rose	146,630	2,360,780
McKinley-Darragh	109,130	2,251,550
Nipissing	66,070	2,379,74
O'Brien	.....	543,77
Peterson Lake (Little Nip.)	.....	58,48
Provincial	.....	40,51
Right-of-Way	.....	378,46
Silver Cliff	.....	106,68
Standard Cobalt	.....	44,81
Temiskaming	64,910	775,30
Trethewey	.....	528,63
Wettlaufer	.....	117,23

The shipments for the week were 694,757 pounds, or tons.

The shipments from Jan. 1 to May 19 were 18,621,885 or 9,310 tons.

Following are the shipments from the Cobalt camp fo week ending May 26, and those from January 1, 1911, to

	May 26. Ore in lbs.	Since J Ore i
Badger	.....	55,20
Bailey	.....	40,00
Barber	.....	6,00
Beaver	58,850	716,70
Buffalo	107,120	1,168,95
Chambers-Ferland	.....	511,80

Other mines	.....	42,005
Total	6,001	143,710

The total receipts at the smelters for the week, including concentrates, were 35,906 tons, and for the year to date, 772,615 tons.

LE ROI NO. 2.

Le Roi No. 2.—Josie mine report for April—Shipped 2,350 tons of ore and 154 tons of concentrates. The receipts from smelter are $33,857 (£6,981), being payment for 2,133 tons shipped, and $3,055 (£630), being payment for 108 tons concentrates shipped—in all $36,912 (£7,611). Estimated costs for corresponding period—Development, $10,000; ore production, $9,000; milling, $1,500. Total, $20,500 (£4,227). Other expenditure, $2,000. Holywell drift, 500 feet level—Advance, 83 feet, of which 64 feet averaged 1 ounce 7 dwts, gold and 3⅛ per cent. copper over 9 inches. Annie drift, 1,300 foot level —Advance, 126 feet.

TORONTO MARKETS.

May 27.—(Quotations from Canada Metal Co., Toronto).
Spelter, 5.50 cents per pound.
Lead, 3.65 cents per pound.
Antimony, 8 to 9 cents per pound.
Tin, 44 cents per pound.
Copper, casting, 12¾ cents pr pound.
Electrolytic, 12¾ cents per pound.
Ingot brass, 8 to 12 cents per pound.

May 27.—Pig Iron—(Quotations from Drummond, McCall Co., Toronto):—
Summerle No. 1, $22.50 (f.o.b. Toronto.)
Summerlee No. 2, $22.00 (f.o.b. Toronto.)
Midland No. 1, $19.00 (f.o.b. Toronto.)
Midland No. 2, $19.00 (f.o.b. Toronto).
Hamilton No. 1, $18.00 (f.o.b. Hamilton.)
Hamilton No. 2, $17.50 (f.o.b. Hamilton.)
Clarence, $19.00 (f.o.b. Toronto).
Cleveland, $19.00 (f.o.b. Toronto).

GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75.
Coal, bituminous, $3.50 to $4.50 for 1¼-inch lump.

Coke.

May 24—Connellsville Coke:—
Foundry coke, prompt, $1.90 to $2.00 per ton.
Furnace Coke, prompt, $1.50 to $1.55 per ton.

May 24—Tin, Straits, 44.40 cents.
Copper, Prime Lake, 12.37½ cents.
Electrolytic copper, 12.20 cents.

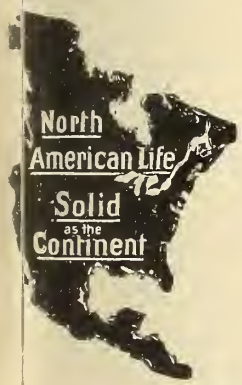
Prompt and Satisfactory Returns



The North American Life is continually receiving from policyholders unsolicited letters like the following, expressive of their appreciation of the treatment accorded them and results attained:

The holder of Policy No 8192 wrote:—
"I appreciate the promptness with which you have remitted the amount due me. I may say that I have nothing but praise for your company for the very satisfactory way in which I have always been treated. Our business relations have been very pleasant and I wish the North American Life the future success it so well merits."

The holder of Policy No. 9205 said:—
"I cannot close matters with the company without expressing my great appreciation of its methods and the very fine manner in which I have been treated by its representatives. In the 20 years of dealing I can recall no single instance in which I have received anything but courtesy and business promptness. I hope to renew relations with the North American soon in respect to my children's insurance."

The Financial Position of the Company is Unexcelled.

Nissen Stamp Mill

The Nissen Stamp Mil

STAMP. The Nissen Stamp drops with great crushing effect up a feed comparatively free of the fines caused by preceding impac This causes an actual splash which radiates from the centre of the d carrying the pulp to a circular screen, every aperture in which prese a full opening for the pulp which has already reached size to p through. As the stamp ascends preparatory for the succeeding blow partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated ty "B" Nissen Mortar.

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

whether you mill, smelt or ship your ores you must have assays and analyses of unquestionable accuracy reported to you in the shortest possible time. Our equipment is especially designed to meet these requirements.

WE also test ores in a practical way to determine just what metallurgical process is best adapted to it to secure the highest commercial results. Write us for prices for your particular problem.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wi a large part of Canada, with many local areas and special subjec

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definately the precise area c cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for wh it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Min Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.

NEW BRUNSWICK and NOVA SCOTIA

1107. Joint Report on the Bituminous or Oil Shales of New Brunswick and Nova Scotia. Also on the Oil Shale Industry of Scotl Part I, Economics, Part II, Geology by R. W. Ells.

QUEBEC

1077. Memoir No. 7, Geology of St. Bruno Mountain, Quebec, with maps, by J. A. Dresser.

ONTARIO

1059. A Geological Reconnaissance of the region traversed by the National Transcontinental railway between Lake Nipigon Clay Lake, Ontario. Accompanied by two maps covering the region, by W. H. Collins.
1082. Memoir No. 6. Geology of the Haliburton and Bancroft Areas, Ontario, by Frank D. Adams and Alfred E. Barlow.
1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.

NORTH WEST PROVINCES

1035. Coal Fields of Manitoba, Saskatchewan, Alberta and Eastern British Columbia accompanied by a map, by D. B. Dowling.
1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1093. Memoir No. 2. Geology and Ore Deposits of Hedley Mining District with maps, by Charles Camsell.
1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1101. Memoir No. 5, Lewes and Nordenskiold Rivers Coal District, Yukon Territory, by D. D. Cairnes.
1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1902, A. W. G. Wilson.

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners, Chilled Wheels and Castings of all descriptions.

THE
SUDBURY CONSTRUCTION & MACHINERY CO.
LIMITED
SUDBURY :: ONTARIO

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rig must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Ce an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affid that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above a mining concession may be acquired at any time at the rate of $10 an acre SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of height of land, where important mineralized belts are known to exist.

Special arrangements have been made with Polytechnic School of Laval University, Montreal, for the determination, assay analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equip laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS

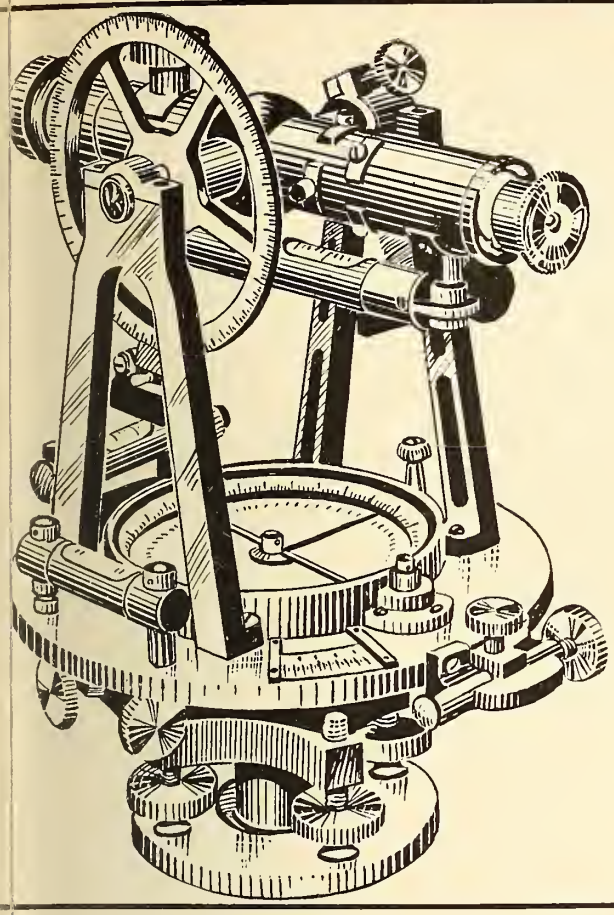
An Ore Merchant who has connections with all blast-furnaces and electro-metallurgical firms of Fra desires to communicate directly with firms who prod or sell:—

Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take r Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.



High-Grade Transits

Keuffel and Esser Transit No. 5165

This transit is designed to meet the requirements of the mining engineer. It is a sturdy instrument and will stand the roughest kind of work. It weighs 10¼ lbs., telescope 9 ins., object glass 1 in., vertical limb 4 ins., horizontal limb 5½ ins. All graduations on solid silver. Four leveling screws of solid German silver.

Instrument complete with tripod - **$195.50**

Instruments of this make are recognized all over America to be of the highest standard of manufacture. Every instrument carries with it our unqualified guarantee.

Another value that will interest surveyors is our Railroad Dumpy Level at **$80.**

And you'll find here a splendid selection of engineers' chains, steel and cloth tapes, tracing linen, etc., of the most dependable kinds.

Optical Section, Second Floor.

THE T. EATON Co LIMITED
TORONTO CANADA

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17 25,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

The Best New Books for Mining Engineers

Just Issued

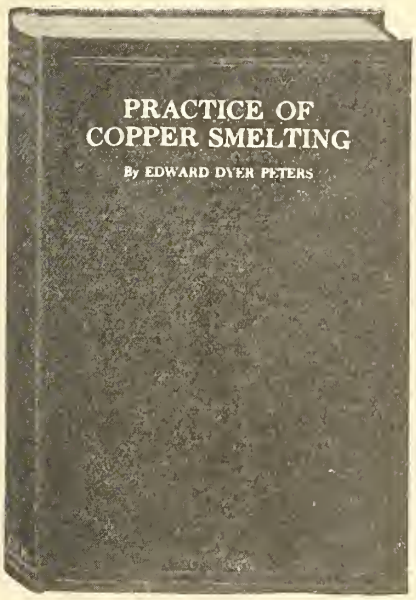
Practice of Copper Smelting

By EDWARD DYER PETERS.
Professor of Metallurgy, Harvard University.

63 pages, 6x9, illustrated $5.00 (21s.) net, postpaid.

This new work is devoted to the modern, actual methods of Copper Smelting with just enough of the principles to give a clear picture of the reasons for each stage of the operation.

It is the fruit of the author's wide experience and extensive research coupled with the information offered by the principal American Smelting Companies.



Dr. Peter's book presents many important matters which cannot be found elsewhere. It tells of the use of Oil as fuel in reverberatory smelting; pulverized coal in reverberatories; modern converter practice with actual results and costs; the basic lined converter with plans; "Fines"; "Slags"; etc.

It is a companion volume to "Principles of Copper Smelting"

Principles of Copper Smelting

612 pages, 6x9, $5.00 (21s.) net, postpaid.

Modern Copper Smelting

600 pages, 6x9, $5.00 (21s.) net, postpaid.

Mining Books

Underground Surveying

Corrected Edition.
By LOVAL W. TRUMBULL, E.M.
250 pages, 6x9, illustrated, $3.00 (12s. 6d.) net, postpaid.

Compressed Air

By ELMO G. HARRIS, C.E.
Professor of Civil Engineering, University of Missouri School of Mines.
136 pages, 6x9, illustrated, $1.50 (6s. 6d.) net, postpaid.

Timbering and Mining

By W. H. STORMS.
300 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

Principles of Mining

By H. C. HOOVER.
200 pages, 6x9, illustrated, $2.50 (10s. 6d.) net, postpaid.

The Cost of Mining

By JAMES RALPH FINLAY.
41 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Tables for The Determination of Minerals

Rock Drills

Design, Construction, Use

By EUSTACE M. WESTON
367 pages, 6x9, illustrations, $4.00 (17s.) net, postpaid.

Describes the leading modern makes of English, Australian and American drills. It assists in choosing machines most suited to particular needs, and using them with the greatest efficiency.

Practical Shaft Sinking

By FRANCIS DONALDSON, M.E.
143 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

The author presents an immense amount of good material in a small space. It is a *timely* volume for mining engineers.

Principles of Metallurgy

By CHARLES H. FULTON,
President and Professor of Metallurgy, South Dakota School of Mines.
536 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

The standard work on this subject. The treatment of the subject is modern. The author presents new ideas, and the style is clear and terse.

Books on Metallurgy

Clennell's Cyanide Handbook

By J. E. CLENNELL.
526 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Ore Dressing

By ROBERT H. RICHARDS,
Professor of Mining and Metallurgy, Massachusetts Institute of Technology.
Four volumes, 2,000 pages, 6x9, illustrated, per set, $20.00 (£4 4s.) per volume, $5.00 (21s.) net, postpaid.

Elementary Crystallography

By W. S. BAYLEY, PH.D.,
Associate Professor of Mineralogy and Economic Geology, University of Illinois.
236 pages, 6x9, 300 illustrations, $2.00 (8s. 6d.) net, postpaid.

Metallurgy of Lead

and the Desilverization of Base Bullion

By H. O. HOFMAN.
600 pages, 6x9, illustrated, $6.00 (25s.) net, postpaid.

Metallurgical Calculations

By JOS. W. RICHARDS.
Three volumes, each volume over 200 pages, 6x9, $2.00 (8s. 6d.) net, postpaid per volume.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

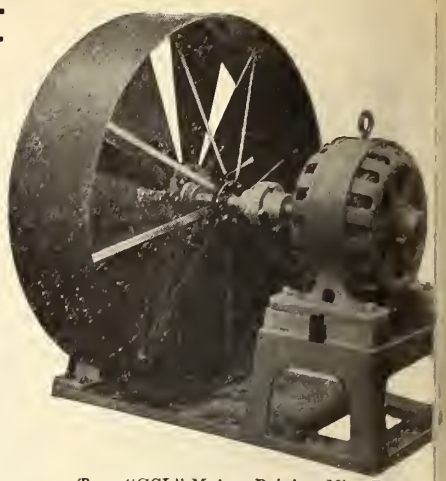
MONCTON, N.B.

You can sit in your office miles away and start or stop your mine fans by simply closing or opening a switch, if they are driven by the right type of motors.

Westinghouse Motors

Type "CCL For A. C. Circuits



Type "CCL" Motor, Driving Mine Fan.

consist of two essential parts the stationary and rotating. No auxiliary apparatus is required except a two-way main switch with auto transformers, giving a low E.M.F. for starting. *This may be located at any distance from the motor.*

Type "CCL" Motors are characterized by strong construction, self-oiling bearings, great overload capacity, low operating temperatures and high efficiency and power factor.

They are applicable for general power purposes requiring continuous constant speed operation and may be belted, geared or direct-connected to the load.

Renold Patent Silent Chains

What Users Think

MONTREAL, Feb. 8, 1909.

Messrs. Jones & Glassco, Montreal.

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your enquiry of Jan. 30th, I may say hat the Renold Silent Chain Drives we have installed are giving very satisfaction.

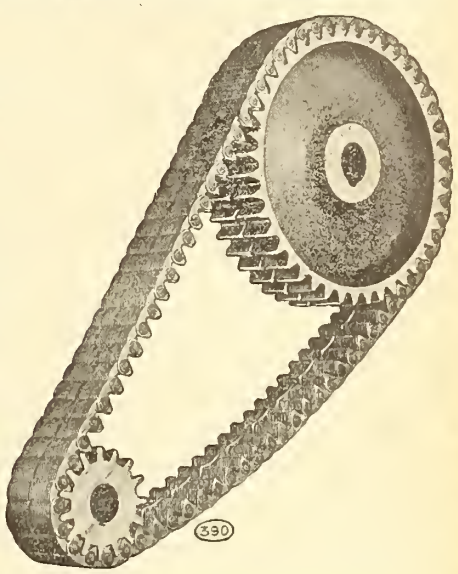
Our first drive was installed to replace a 12 in. belt which was ıving us trouble on account of short centres; this chain has run con-ınuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy uty and which had previously broken up two sets of spur gearing; his chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after reaking two sets of helical gears and this has been so successful that ve are now installing two more similar drives.

I would be perfectly willing to make an appointment with any erson genuinely interested and show him the drive in operation.

—The above comes from one of the largest manufacturers in Montreal and is signed by the echanical Superintendent. Up to the present (1911) these drives have not received repairs any kind.



Write for particulars.

Sullivan Stope Drill in a copper mine

STOPING

raising, or upper hole drilling for any purpose will cost you least per foot of hole, or per cubic foot of ground removed, if your drills are

Sullivan "DA21" Stopers.

Mine Managers who have conducted severe tests with Sullivan Stopers and with other makes, will tell you that this is so. They will tell you, too, that **great speed, high power economy,** and **remarkable freedom** from **breakage** and **wear** are factors in accomplishing this result.

Runners will tell you that the "DA21" works more **smoothly** and with **less jar** and **vibration** than other tools; also that it is easy to clean and care for because it contains **no screw joints,** and every part can be reached by loosening three nuts.

We want to tell you more about **what** this drill is doing and **how** it is able to do it.
May we send bulletin "660 D?"

Vertical Plunger Sinking Pump

CAMERON MINE PUMPS

HAVE Stood the test of use for fifty years, in every clime and under all conditions.

You all know the Reliability of the Cameron ; it's a bye-word in Mining Circles.

You know all about its steam economy and how it is impossible for the piston to strike the heads or do any damage should the supply of water be cut off and the pump allowed to run away; how it will start at any point of the stroke and most important of all, that there are fewer working parts than in any other pump.

Knowing all this, why should you hesitate about what pump to install? Ask someone who is using the Cameron.

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

LONG LIVE THE KING!

The Coronation of King George and of his consort Queen Mary will have taken place in a few days. From all parts of the Empire British citizens have flocked to London to see the imposing pageant. From Canada alone, hundreds of official representatives and many private persons are now eagerly awaiting the day in London. But not in London will all loyalty be concentrated. Throughout Canada, as throughout all the Imperial domains, there is evident the warm throb of an Empire's devotion.

To Canadians the event is fraught with deep significance. The fates have ordained that of all Great Britain's self-governing children Canada should now be the strongest and most assertive. We have thrown off the swaddling clothes of infancy and are becoming conscious, perhaps too conscious, of waxing strength and growing bulk. But no diminution is apparent in the whole-heartedness with which we acclaim the accession of our titular head to the Imperial throne. Not even does the proposed readjustment of international trade relations dim the lustre of the occasion. But the fact that Canada has so large a voice in the Imperial Conference and the fact that weighty matters affecting the whole Empire are now under discussion at a time when the eyes of all civilized nations are turned towards London, make the present momentous.

It is not to be doubted that our cautious and astute Premier will refuse to commit his country to any fantastic antipodean scheme. Commerce and sentiment rule the world. Sentiment is apt to hold the reins when excitement runs high. Hence the danger at such a time as this.

But there is also the danger of failing to read the real meaning of a nation's existence. Commerce is not everything. We are perhaps quite as much swayed by considerations that have nothing to do with worldly gain, as by those that have. And, first and foremost, we neither wish nor intend to beg commercial or other favours of any nation on the face of the earth. A nation young, vigorous, and neither morbidly modest nor vauntingly vain, we desire above all to retain our identity, to work out our own destiny, and to live in harmony with our neighbours.

Yet, like the unassuming porcupine, an animal that goes its own way without molestation, we must prepare ourselves for self-defence. On the Atlantic and on the Pacific we possess vast coal resources. What the capture of these by a hostile power would mean may be left to the imagination. In this and other respects we are a standing temptation to any probable rival of Great Britain. Hence the tremendous import of the deliberations in London.

The pomp and circumstance that mark the Coronation are not idle display. The whole huge ceremonial will be not alone an opportunity for the exchange of courtesies between Great Britain and her sister nations—it will be a majestic demonstration of the fact that in power, in prestige, and in dignity Great Britain has gained ground. And it is peculiarly inspiring to think that from what were "colonies" and now are "Dominions" comes the moral and material support that the Mother Country needs.

There is another side, however. To Great Britain we owe the most profound debt that nation can owe to nation. Without Great Britain in the background our treaty-making, our plans for defence, and, indeed, our commercial development were a farce. To her navy, and to her gold, must be attributed a surprising proportion of our prosperity. The debt of obligation is still ours. This is sentiment, but it is sentiment that can be utilized as an impelling force in regulating, first, our commerce with the Empire, and. second, our commerce with other nations.

* * * * *

The King is soon to visit Canada. The welcome that he will receive here, unbounded as it may be, will express but feebly the desire of every true Canadian to be true to Canada and to the Empire.

A MODERN INSTANCE.

As an illustration both of the urgent need of revision of the regulations under which the Department of the Interior, Ottawa, administers Federal lands, and also of the anomalous situations that may arise, we shall recite here an actual instance that took place a few weeks ago.

Two men made application for a coal mining location in the west covering 5,160 acres. All the requirements of the regulations were fulfilled as regards staking, making proper application, and making the necessary deposits of $5 each. The stakers had then thirty days from the date of staking wherein to put in their application. After that application had been considered favourably by the Department at Ottawa, a process covering two months, they were given another thirty days in which to make payment of the annual rental of $1 per acre, a total of $5,120.

Being unable to raise the money, the men went to the place and, on the morning when their claims would have been cancelled for non-payment of the rental, they restaked the claims. Thus they succeeded by a very simple evasion of the law, in postponing payment of the rental for another three months.

This process might go on indefinitely. For obvious reasons it would be neither practicable nor seemly for anyone else to attempt to jump the claims. For equally obvious reasons it is not well that the regulations encourage this kind of evasion.

It has been suggested that the immediate payment of one years' lease—$1 per acre—be required, and that provision be made to return this money in case lands prove not available. No doubt this would more business-like. It might, of course, become a h ship to the prospector. But, as under present co tions the prospector is legally obliged to pay this a age tax and as only by acting contrary to the s of the regulations can he avoid payment, it is illog to continue the system that now obtains.

The loss of time, the sickening delay, the misun standings that arise in trying to control from Ott coal lands in the far west, are no longer tolerable. the Minister of the Interior a knowledge of mining vestment, or even a sense of humour, he would vo tarily forego the privilege of breeding confusion, st and all the ills that are engendered by long-dist maladministration.

PROSPECTING FOR GOLD.

In our issue of April 15, 1911, we referred editor at some length to a paper read by Mr. W. H. Pres the subject of prospecting in Nova Scotia. The p in question was a short and succinct presentatio the problems that confront the prospector and of methods that had best be followed.

In this issue of the CANADIAN MINING JOURNAL readers will find an ampler and far more compre sive view of the matter. Not only do the princ and points enunciated bear specifically upon Nova tian gold mining, but they also apply with equal to certain large tracts in New Brunswick and Qu that are known to be gold-bearing.

The moral that is deducible from Mr. Prest's a is that prospecting must be controlled by com sense. The vague wanderings of the boulder-crac bushman are of little use. The academic meande of the pure geologist are of less use. Only the ar and intelligent labours of the trained modern pector are calculated to bring results. The thoug man will know instinctively just what geological is of use to him, and he will use it along with his excogitations.

We firmly believe that, if the right steps are t Nova Scotia will yet vindicate itself as a gold-mi country. In any case, nothing could be more oppo than Mr. Prest's paper. We commend and endor

The Ontario Bureau of Mines has made an add to its staff in the person of Mr. T. F. Sutherland, is to be Assistant-Inspector of Mines. Mr. Suther is a graduate of the Kingston School of Mines. years ago he suffered his apprenticeship in the mines of Eastern Ontario. Since graduation he spent seven or eight years in mining in south-ea British Columbia and Portland Canal. He also miliar with Cobalt and Porcupine. Mr. Sutherl appointment, we confidently expect, will meet approval.

THE NATURAL ASSOCIATIONS OF GOLD.

Because in some senses the geology and metallurgy of gold are simple in principle there are many simple facts that are either overlooked or not co-ordinated.

In the current number of Economic Geology, Mr. Francis Church Lincoln contributes a long monograph on the natural associations of gold, dividing his subject into two parts—the associations of gold with rocks, and the associations of gold with minerals.

It is impracticable to touch upon more than a few features of Mr. Lincoln's paper. All of it deserves close study.

Discussing the impregnation and replacement of rock in the neighbourhood of a vein, the writer points out that in all probability the extent of these phenomena is not yet fully appreciated. Gold reported as primary may in reality be secondary. Samples that are taken at a safe distance from known mineralization may really represent rock that has undergone secondary enrichment. Microscopic examination of thin sections is the only certain means of determination.

The assayer's "trace" usually means less than ten cents per ton avoirdupois, equivalent to 166 milligrams per metric ton. In 46 tabulated assays of igneous rocks only four are recognized as absolutely indicating primary gold. The rest are set down as either "probable" or "possible." Of 25 of these rocks, seven are basic, six are intermediate, and twelve acid. Disregarding abnormally high results, the normal gold content of these igneous rocks appears to be between 60 and 80 milligrams per metric ton. The distribution of gold seems to be somewhat even, irrespective of the chemical composition of the rocks. But the data collected are too incomplete to admit of drawing definite conclusions. What evidence there is tends to prove an irregular distribution of minute amounts of gold and silver in igneous rocks, the gold averaging about four cents per ton avoirdupois, and the silver about six cents. There is no marked difference in gold content as between acid and basic igneous rocks, while silver content basic rocks are probably slightly higher than acid rocks.

Sea water, sub-crustal waters, rock salt, clays, coal, and many organic substances contain gold in pondérable amounts. One coal has been reported from Wyoming containing $1 to $5 per ton.

Gold occurs in sedimentary rocks almost universally. Pro determinations reported the value is roughly one cent per ton. The general conclusion appears to warrant that the coarser the rock the higher the gold content.

The origin of gold in completely metamorphosed rocks is a matter of speculation. Primary gold has been mined in metamorphic rocks and has been won commercially from important placer deposits.

Generally, no evidence can be adduced to show that the gold of igneous rocks segregates in the more basic or the more acid members. It has been seen that there are few authentic occurrences of primary gold in igneous rock. The concentration of 3½ cents in gold per ton in the same ratios that have obtained in known magmatic segregations of iron, nickel, and chromium, would develop ores running from a few cents to $144 per ton. No such segregations of gold have been found. The Klondike gold has been estimated by Mr. Lincoln to represent a saving of 2 cents per ton of rock (sedimentaries) eroded. But no commercially important placers derived from igneous rocks are known. Thus the assumption of extensive magmatic segregation of gold in igneous rocks is not justified by available facts.

We have outlined above, with many serious gaps, the trend of the first section of Mr. Lincoln's article—the section dealing with associations of gold with rocks. The last paragraph synopsises the geologic history of gold — the distribution through the igneous magma, the concentration by erosion, the formation of coarse- or fine-textured rocks with higher gold content, the metamorphism of these sedimentaries, etc. It is pointed out that, though of economic interest, veins are quantitatively unimportant.

The second part of the paper space does not permit us to cover. A lengthy discussion of the mineral associations of gold, well illustrated with diagrams and photogravures of rock slides, is followed by conclusions that briefly outline results so far attained. As throwing light upon the extraordinary richness of many ores in which no gold is visible either to the unaided eye or under the microscope, it is suggested that the same relations exist between gold and other minerals on a sub-microscopic scale as exist on microscopic and macroscopic scales.

* * * *

Few more instructive essays have appeared than this of Mr. Lincoln's. It should be read and digested.

THE DIFFUSION OF CAPITAL.

Mining booms are not unmitigated evils. They stir up public interest, and are instrumental in disseminating all kinds of mining news. From the Rossland boom there have survived several strong organizations. Likewise has the Cobalt boom brought into existence scores of prosperous operating companies. Both booms taught their lesson, and both brought ultimate good to the country. This does not by any means imply that we approve the boomster.

Looking back over the rise of Cobalt there are many incidents that, considered together, prove that New Ontario has done considerably more for Old Ontario than has the Old for the New. The impressive array of new houses built by Cobalt money in the best residential sections of Toronto, not to speak of multitudinous motor cars, is direct evidence. Some millions of dollars of money made in Cobalt have been invested in real estate in Toronto. Montreal, also, can

boast more than one modern business structure that owes its existence to Cobalt profits.

There is evident now another effect of capital created in New Ontario. Cobalt men and their associates are purchasing and developing mines in British Columbia, in Western and Eastern Ontario, in Quebec, and in Nova Scotia. Sheep Creek, B.C., Sturgeon Lake, Ont., and Killag, N.S., are some of the most notable illustrations. At these three localities investors who have been directly identified with Cobalt are supplying the necessary money.

Porcupine is really the child of Cobalt. In what condition Porcupine would now be were it not for Cobalt shekels we can only surmise. Porcupine, however, will be the means of infusing life into other mining camps, more especially, we think, into old mining camps that have fallen by the wayside.

Thus Cobalt and Porcupine are not provincial but national in their influence. The boom that is impending in Porcupine will carry in its train less of misfortune and more of good exactly as the investing public is correctly informed as to facts. If the camp survives the boom, every other gold-mining region in Canada will, sooner or later, reap the benefit.

This is the large meaning of successful mining. No other industry calls into play such immediate enthusiasm, nor does any other industry diffuse so widely the wealth that it begets.

EDITORIAL NOTES.

In our report of the annual general meeting of the Maritime Oilfields, published in our issue of May 15, we omitted mention of the fact that Dr. J. A. L. Henderson was the chairman. As his brother, Mr. W. Hope Henderson, is also on the board, the correction is made to prevent confusion.

The Canada Refining and Smelting Company's plant at Orillia is the latest addition to our Cobalt ore smelters.

BOOK REVIEW.

THE DAVIS HANDBOOK OF THE PORCUPINE GOLD DISTRICT—WITH A DIRECTORY OF INCORPORATED COMPANIES—By H. P. Davis—131 pages — Illustrated — Price, Paper Cover, $1; Cloth Cover, $1.50 — Published by H. P. Davis, 25 Broad Street, New York.

Mr. Davis' work in connection with Cobalt is known to many of our readers. The Davis Cobalt Handbook proved to be a boon as a ready source of reference. The Porcupine Handbook should be equally useful. Among its contents are an historical review, a directory of incorporated companies, an outline of the geology of the region, a description of some important properties, and a claim-map.

It is Mr. Davis' intention to revise the book from time to time.

As mentioned in our editorial columns, this volume is not to be confounded with the book now being brought out by the Canadian Mining Journal. two books are of widely different character. To a l extent they supplement each other.

PERSONAL AND GENERAL.

Mr. Mosco Vici, mining engineer of Monti against whom suit was brought by Mr. James A. Br of the same city, was honourably acquitted rece by Judge Langelier in the Court of Sessions. The had been decided some time ago; but, on Mr. M Vici's request, a re-hearing was granted. The mer decision did not completely exonerate him; latter decision does.

Mr. R. B. Lamb is in Porcupine.

Mr. Frank Loring is inspecting properties aro Sturgeon Lake.

Mr. O. N. Scott has returned from Europe.

Mr. J. Eakins, formerly manager of the Fo O'Brien, is in Toronto.

Mr. J. W. Astley has taken an office at 13 Mann Arcade Annex.

Mr. George F. McNaughton is staying for a sh time at the Arlington Hotel, Toronto.

Mr. Robert S. Stewart, of Trail, B.C., general ma ger of the Consolidated Mining and Smelting Comp of Canada, Limited, was in Toronto during the la part of May.

Mr. Frederic Keffer, of Greenwood, B.C., mining gineer for the British Columbia Copper Company, L has been to Franklin camp, north fork of Kettle Ri to arrange for commencing exploratory work on McKinley group, lately bonded by the company un option of purchase.

Mr. H. Mortimer-Lamb, secretary of the Canad Mining Institute, has returned to Montreal fron visit to British Columbia.

Mr. Alexander Sharp, of Orient, Washington, U.S mining engineer for Mr. P. Burns and associates about to remove to Calgary, Alberta, where his he quarters will be in future.

Mr. H. G. Stehli, superintendent of the Dwigh Lloyd Metallurgical Company, of New York City, been at Trail, B.C., superintending the starting of of the company's sintering plants, put in at the C solidated Company's smeltery.

Mr. Albert I. Goodell, formerly manager of the Mc real & Boston Company's copper smeltery at Bound Falls, B.C., and afterwards of the Le Roi Mining C pany's smeltery at Northport, Washington, U.S.A. now buying ore for the International Mining and Sm ing Company, of Salt Lake City, Utah.

Mr. C. P. Hill, managing director of the Hille Coal and Coke Company, has returned to western berta from a visit to Porcupine, Ontario.

Mr. I. L. Merrill, of Los Angeles, California, pr dent of the Hedley Gold Mining Company, and Mr. Walter Beam, of Denver, Colorado, have returned the United States from a visit to the company's Nic Plate mine and stamp mill in Similkameen distr British Columbia.

Mr. R. P. Williams, for many years representative western Canada of the Canadian Rand and Jene Machine companies, has entered the joint employ the Canadian Rand Company, Montreal, and the gersoll-Rand Company, of New York. He will w in connection with the Vancouver, B.C., and Seat Washington, offices of those companies.

PROSPECTING IN NOVA SCOTIA.

Written for the Canadian Mining Journal by
W. H. Prest.*

Having been asked to contribute a short paper on prospecting in Nova Scotia, I find it difficult to separate the actual work from the geological problems with which they are intimately associated. In fact, the methods and distribution of work can hardly be described without giving the reasons for such distribution and these reasons are chiefly geological. The mere sinking of pits and opening of trenches without system is not prospecting. Systematic work in this line means a programme arranged after a fair preliminary knowledge of rock structure, surface distribution, and origin of debris. This is all that can be learned by a surface examination and only serves as a guide to the location of trial pits. The first work in jobs of this kind in Nova Scotia is nearly always experimental and only lays bare local peculiarities of drift distribution. Only then can a method of working be devised that will insure economy and success. The following working programme seems to me to be most suitable for deep surface such as we have in Nova Scotia.

Location.

Prospecting in Nova Scotia is as a rule a far different matter from prospecting in Ontario and the west. In our circumscribed areas the wandering prospector has little place. The chance surface finds are nearly all made, and the prospector makes his home in or near an established mining camp. The largest area not intersected by good roads is a tract of about 1,000 square miles in the western part of the province, and it is only there that the prospector goes to his work in western style. The prospector's duties are now chiefly confined to tracing float and, as this is usually done in deep surface, his sphere of operations is limited. Within the limits of each district are usually two or three localities noted for the discovery of rich float. This is usually held under lease or license as our too liberal mining laws have resulted in nearly all mining land of any value being held without working conditions. This state of affairs leaves little new land worth prospecting, and if the owner does not or cannot do the work it remains undone. Rich float was found on some properties nearly 50 years ago, the source of which has not yet been discovered. Therefore the prospector is usually hired as he can seldom afford to work on shares and pay those who help him.

As a rule, the gold mining districts are well defined and surveyed, and within the limits of these districts nearly all the prospecting in Nova Scotia is done. The five counties of Guysboro, Halifax, Hants, Lunenburg, and Queens, contain nearly all the gold mines in Nova Scotia. In these counties are 50 or 60 localities in which rich float has been found, indicating the existence of still undiscovered veins. The search for these hidden veins is the work of the prospector of the future. It is not likely that much more rich float will be found on the surface, as even the farmers invariably examine and break every piece of quartz or heavy rock they find. But the float already found points to many years of trenching and shaft sinking. In them we have the source of much probable profit as some of this float is very rich.

*Mining Engineer, Bedford, Nova Scotia.

Outfit.

In the early history of gold mining in Nova Scotia a prospector's outfit would not have called for much comment—a pick, a pan, a kettle, an axe, a few pounds of food, and the inseparable pipe, tobacco, and matches. Tent and blankets were luxuries to be despised by any man who desired an honourable reputation for hardihood. Camp and dishes grew on every white birch tree and every prospector had Indian lore enough to strip the bark and make them.

Now, however, all this is changed. The work is harder, the surface is deeper, and the prospector more particular. Now an outfit for ordinary work will include, say, one dozen heavy cast steel single pointed picks, one-half dozen long-handled pointed steel shovels for surface work, three short-handled pointed steel shovels for underground work, one stone hammer, one striking hammer, one blacksmith's hammer, one crowbar, one prospecting pick, one half-dozen short drills, one miner's spoon, two axes, three zinc pails, one gold pan, one pocket lens, one pocket compass, one handsaw, one blacksmith's file, two saw files, one cold chisel, one pair tongs, one 1½-inch augur, one keg (100 lbs.) of mixed 5 and 7-inch spikes, 25 pounds 3½-inch nails, ⅜-inch rod iron, hoop iron, one iron bound rock tub, one water barrel, 50 feet 1-inch rope with grummet, one 5-foot x 5-inch windlass with cranks and standards, one portable forge, one combined anvil and vice, one diaphragm hand pump with 2½-inch suction. Repair material for forge, pump, tub, and windlass. Lumber (1-inch) for spouts and other purposes; 1½-inch lumber for lagging, dump box, etc. Dynamite fuse and detonators, say enough for 20 shots. Camping and cooking outfit for at least four men. At least one month's provisions. A boarding house or even an empty house near by will greatly facilitate the work. The modern prospector in Nova Scotia must be prepared for trenching, shaft sinking, or tunnelling as conditions demand. The outfit also includes to an extent that it never did before, a knowledge of structural and glacial geology. In the new order of things the wandering prospector occupies but little space, therefore I can be excused for not describing farther a fast-vanishing phase in this occupation.

Before leaving this part of the subject I may say that the pay of a cook is often saved for more effectual work by including a few barrels of hard bread in the provision list. Not the kind that weak-mouthed home-stayers usually call hard tack, but those that the old-time British tars used to repel boarders with. Compact and nourishing, but durable as wood, I pity the martyrs to toothache who cannot eat them or will not try. My toothache stopped when I began their use twenty years ago.

Mapping.

This important preliminary to prospecting is usually neglected here, as elsewhere. If the Government maps have been published they are often used. The general maps are drawn on a scale of 1 inch to 1 mile, the district maps on a scale of 1 inch to 250 feet. These maps, which I may call Mr. Faribault's life work, cover about three-quarters the area of our gold bearing rocks and are well worth the time spent on them. Once done, the work will last for many generations. The struc-

tural geology and details of past mining operations are given with as much detail as the scale will allow. But for the prospector's use this information must be supplemented by much greater detail in depth of surface, distribution of drift, and surface contour. Therefore, a special survey should be made connecting with the nearest Government marks, and the results embodied in a map on a scale of at least 40 feet to 1-inch. This will enable details to be noted down even as small as one or two feet. On this plan should be noted down details of geological structure, surface contour, drainage, depth of drift, course of glacial transportation, and distribution of gold bearing float. Position and depth of pits already dug should be noted. These pits, as well as others to be dug, should be numbered and details of each as far as known entered in a note-book for comparison with other work. Previous work should furnish valuable information, but as a rule, through careless observation or exaggeration, the exact truth is hard to get at. Under these circumstances verification is necessary and this can only be obtained by sinking new shafts. A mere sketch map will hardly do, as the amount of money involved is often too much to risk through careless work of any kind. A little practice with an ordinary land compass will enable almost anyone to make a fairly accurate plan of the locality chosen for the work. Mr. Faribault's excellent maps can be used as a basis for a larger and more detailed plan, though it will be some years yet ere his work will reach the western end of the province. One day's surveying should furnish ample information for a working plan.

Panning.

Panning lessens the heavy preliminary work by making the mapped information more effective. It draws within closer limits the boundaries of gold distribution, defines the areas of coarse and fine gold and gives the prospector a centre of distribution as a safe location for pit sinking and trenching. It usually confirms the conclusions derived from the surface distribution of gold bearing quartz and saves the waste of time and labour on large barren areas which formerly characterized prospecting in Nova Scotia.

Panning can be done on samples from old dumps, surface soil, beds of brooks, and the sides of pits and trenches when above water level. About 200 pans, if possible, should be taken and a strictly exact record be kept of all results, viz.: location of samples and number of pans from each location, character and composition of drift (as a clue to its source), and number of colours from each pan. When this is done it will furnish two valuable bits of information, viz.: 1st, where your rich vein probably is, and, 2nd, almost equally important, where it is not.

Information derived from panning to be classified as follows: 1st, colours—divided into four sizes, the smallest seen only with a pocket lens, represented as a,b,c, d; thus 7a, 3b, 4c, 2d, means seven colours of the size a, three colours of the size b, etc. 2nd, sights, divided into four sizes, e,f,g,h; 3rd, shotty gold, divided into four sizes, i, j, k, l. 4th, nuggets, divided into four sizes, m, n, o, p.

Enter on your map a summary of these results by drawing a line around the outer limit of gold distribution. Draw another line enclosing the outer limit of the shotty gold and largest sights. This inner line will enclose your centre of distribution, within which, or at the northern extremity of which, the most of your future work will be done. The character of the debris in which your coarsest gold is found will in cases represent the character of the rock in w your rich vein is located. Two men, a panner a helper, should put this part of the work throug four or five days.

Test Shaft.

Another important part of the preliminary w especially where little or no work has been don fore, is a test pit. This, in order to find out i float gold is present in the upper, middle or l portion, or throughout the whole depth of the d to be cut through in future work. If gold is pr in only the upper layers of drift the source of probably some distance away and the pits ca placed at considerable distances apart and muc bour saved. If the upper layers only contain there is no need to sink through the barren drif low. If gold is present only in the bottom laye deep drift the vein searched for is probably no away and great care should be exercised in the tion of ground for new pits. Various other impo facts may be brought to light which would affect l ly the cost and location of future work. A test should always be sunk to bed rock within the l of the richest pannings or float ore, but near its thern or upper margin. A sectional plan shou made on a scale of 1 inch to 1 foot, or at least enough to contain marginal notes, thus saving con reference to a note book. The following facts shou noted:—

1st. The sub-divisions of drift, with depth, thick slope, mode of formation, and composition of Number each layer for future reference.

2nd. Pan tests of each layer with results grad before mentioned, and noted on plan of shaft a map of areas.

3rd. Absence or presence of gold bearing float, tity and apparent value per ton, number, size, d of wear, and character of each variety, with asso minerals, as a means of identification.

4th. Details concerning bed rock, such as dip, s cleavage, and results and courses of glacial acti

5th. Depth of water level, estimated quanti water per day. This item often bears strong the cost of work.

6th. Size of shaft and number of tubs of hoisted.

7th. Cribbage-cost of material and time.

8th. Number of days' work with estimate of for each part. The last four items are necessary fair estimate of the cost of future work.

All the gold bearing quartz from the test should be kept for comparison with that from shafts. They should be numbered and arranged orderly manner in boxes.

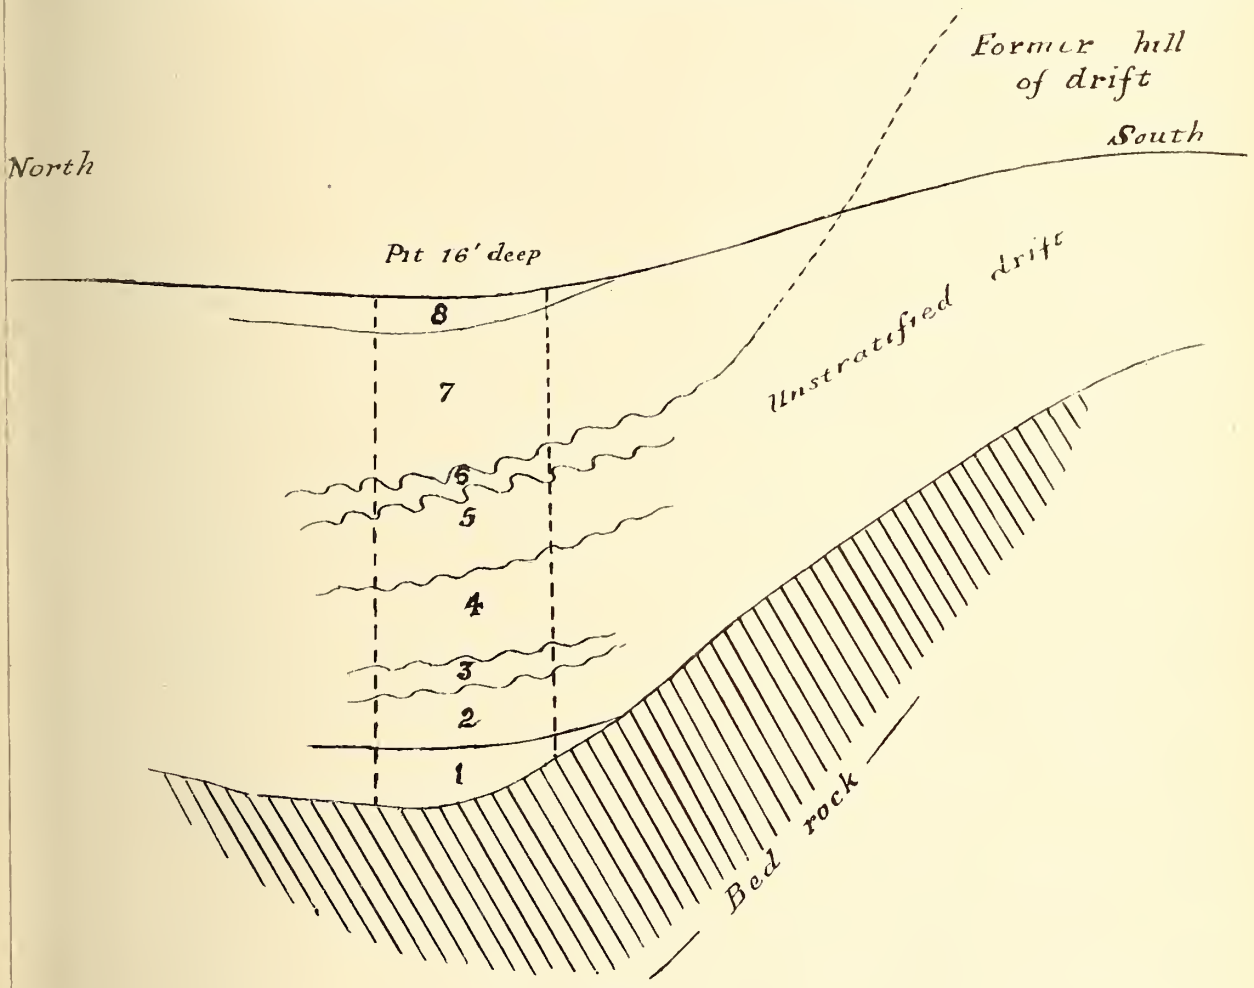
Sectional Plan.

The test shaft finished and the regular work there should be some simple way of showing and at a glance the progress of the work. Fo purpose a sectional plan should be made on a s at least 40 feet to 1 inch. In deep surface such a of facts is very necessary as mistakes under suc ditions would be costly. On this plan should the test shaft as well as every other pit that can cluded in its line of section. The different lay drift could thus be traced through each pit an contents compared and much valuable infor gained concerning the origin and distribution

gold. Details should be entered in a note book mparison whenever necessary.

The Regular Work.

th the understanding that deep surface is as usual operated in, we will describe the next step in the ramme. If help is plentiful two or three pits ould be started in the most likely direction to save me. These pits need not be sunk any deeper than the gold bearing layer, unless strong evidence of post-Glacial action leads us to suspect that the original course of the rich float has been deflected or reversed. Should all these pits be in gold bearing drift, the next set of pits could be put down in the same direction, abreast of each other as in the former case. Should ever, an open trench well bottomed would not be costly. If the sectional plan is on a small scale a plan of each pit should also be kept on which all details of stratification, composition, panning records, and finds of rich float could be entered. These could be compared from time to time and the information gained applied to the work in hand. Of course, we must not expect to find a perfectly orderly arrangement of beds in any one section of mining land. Some pits will contain more or less strata than others, and the corresponding layers may be identified, sometimes by means of a peculiar kind of ore or rock, or by its waterworn condition, or the general composition of the layer, or perhaps by its state of oxidation. Then it is not un-



No 1

t to the right contain no gold the next set of pits ould be sunk farther to the left, and vice versa, er to keep on the course of the drift transportation. The float gold being distributed from the pay-streak in a somewhat fan-shaped form, the area to be prospected will become more and more contracted as you proceed. At last a single pit at each advance will be all that is necessary, except in case of deviation of the float gold from the general course of drift transportation. Approaching the source of the gold the richest float is usually on or near the bed rock. Here the most care is needed in tracing the float, as it is often entirely absent near the vein from which it came. The above procedure is best for deep or fairly deep surface, the sinking of pits only to the gold bearing stratum and their location in well chosen positions saves much time and money. In shallow surface, however, it is common to find two beds containing float gold from the same vein, but these are usually the product of two different periods of erosion and hence are transported in somewhat different directions.

Problems in Prospecting—No. 1.

Inseparable from prospecting in Nova Scotia is the necessity of being able to explain some of the numerous problems in glacial and structural geology, which are continually coming before the prospector. They oppose him at every turn and unless he has a particular aptitude for the study of nature's lessons, fate usually marks him for a failure. Having no capital, it is of little use to talk to him about the employment of a specialist.

Some of these problems are quite simple, while others tax the knowledge of the geologist. The above from Gold River, N.S., is a sample:

1. Deposit of coarse mixed debris with gold bearing quartz, much waterworn and with a current of water running through it to lower land farther east. It was evidently the bed of a brook running over a rich vein farther west.

2. Unstratified drift of quartzite, sand, and clay.

3. Stratified drift, gravel, sand, and clay, with a little gold bearing quartz.

4. Unstratified drift of same character as 2.

5. Stratified drift becoming more sandy and finer in its upper part where it contained some clay.

6. Fine dark clay with pine and spruce cones, beech nuts, birch bark and various seeds and leaves, and remains of water plants and water bugs. The whole was crumpled into small folds.

7. Unstratified drift.

8. Stratified drift, chiefly granite gravel.

This shaft showed gold in the bottom layer. Under ordinary conditions the prospector would search to the north for the source of the gold. But in face of the unusual conditions shown in the plan it was evident that here was a problem needing investigation. Without detailing the various steps in this investigation, I will give the conclusions arrived at. Surface conditions—a high bluff of glacial drift to the south, a lower one to the north, a miry bog—the site of a former lake to the east, a slight ascent to the west. West of this pit about 250 feet was a gold bearing vein. A brook ran from the vein to the pit carrying with it fragments of gold bearing quartz and fine gold, forming bed No. 1, and undermining the bluff or hill to the south. Then came a fall of earth from the bluff forming bed No. 2. This partly stopped the brook but allowed some fine gold bearing material to flow down and form bed No. 3. Then followed another erosive stage resulting in another fall of earth—bed No. 4. This completely stopped the brook and formed a pond which afterward found an outlet toward the west. In this pond the wave wash stratified the upper portion of the last fall of earth into bed No. 5. Then succeeded a period of quiet during which a forest grew and grass, flags, and other water plants filled the pond. Water bugs crawled, cones, nuts, twigs, and leaves fell and were buried and humus accumulated. The presence of beech nuts here led to the further discovery of a former brook flowing north into the pond from a former lake one-half mile to the south. This lake is now a miry bog with a hill on its western side, the only place in the neighbourhood where beech trees can be found. The brook leading from this former lake is now filled with sand carrying gold, the source of which has not yet been discovered.

After a long and quiet period, the whole bluff to the south slid down the slanting surface of the glacier planed rock corrugating the muddy pond border. Then it suddenly gave way and buried the shore line with its vegetation under 5 feet of unstratified drift, forming bed No. 7. Then followed a slow surface wash from the hills on both sides forming the partly stratified bed No. 8. As this shows stratification, the water to which it over must have been turned to the east because of the stopping of the western outlet.

Here is an example in which a moderate knowledge of glacial geology is of great importance. Here was gathered together debris from different sources, transported from different directions, and under different conditions. The source of the rich float in the pit bed would, under ordinary conditions, have been searched for to the north, whereas it came from the west.

Problems in Prospecting—No. 2.

This example is from West Caledonia, N.S. The solution was an accident. For a long time the source of the rich float found here was supposed as usual to be to the north. Though two plans should illustrate this, a careful reading of the text will make it understood.

1. Lead, course N. by W., and S. by E.; the source of the rich float found in the neighbourhood.

2. General course of float transportation during Glacial age.

3. Deflected course of transportation in post-Glacial times.

4. Unmodified drift without gold.

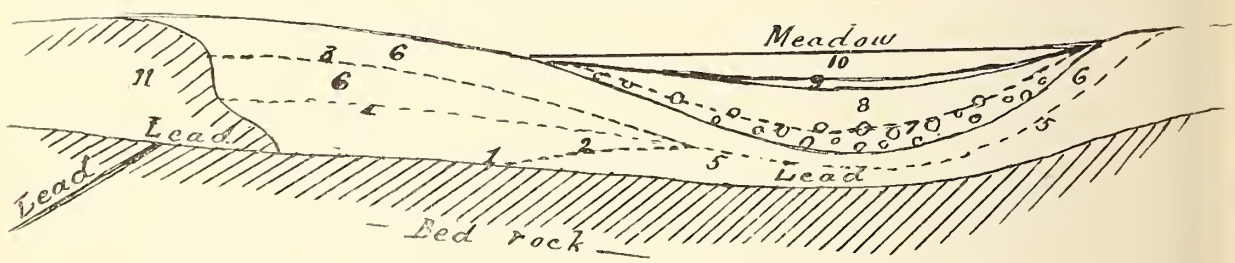
5. Unmodified drift containing gold.

6. Partly stratified drift containing gold.

7. Barren sand, gravel, and boulders from a higher level up stream.

8. Quicksand.

9. Fragments of wood, leaves, water plants and shells.



No. 2.

10. Peat and swamp muck.

The true explanation in this case seems to be the following. The debris from the vein was pushed down a gentle slope to the south by the general glacier. Then during post-Glacial times the gold bearing drift was cut away near its source, by a stream flowing to the southwest. This removed a large part of the drift to the northeast, jamming a gold bearing boulder into a crack in the south side of the bluff or ledge 11. As this boulder could not have been thrust in from the north, I was convinced that this portion of the gold bearing came from the south. In pursuance of this new idea, the vein searched for was soon after found. The expansion and transporting power of ice doubtless was accountable for a large part of the transportation to the northeast. After a time the debris formed a dam about 100 yards down stream. Behind this, gravel and sand accumulated until the brook turned in another direction, left a pond behind it. In this, peat grew and the water gradually drained away until a forest covered the peat, which finally gave place to the present meadow.

Problems in Prospecting—No. 3.

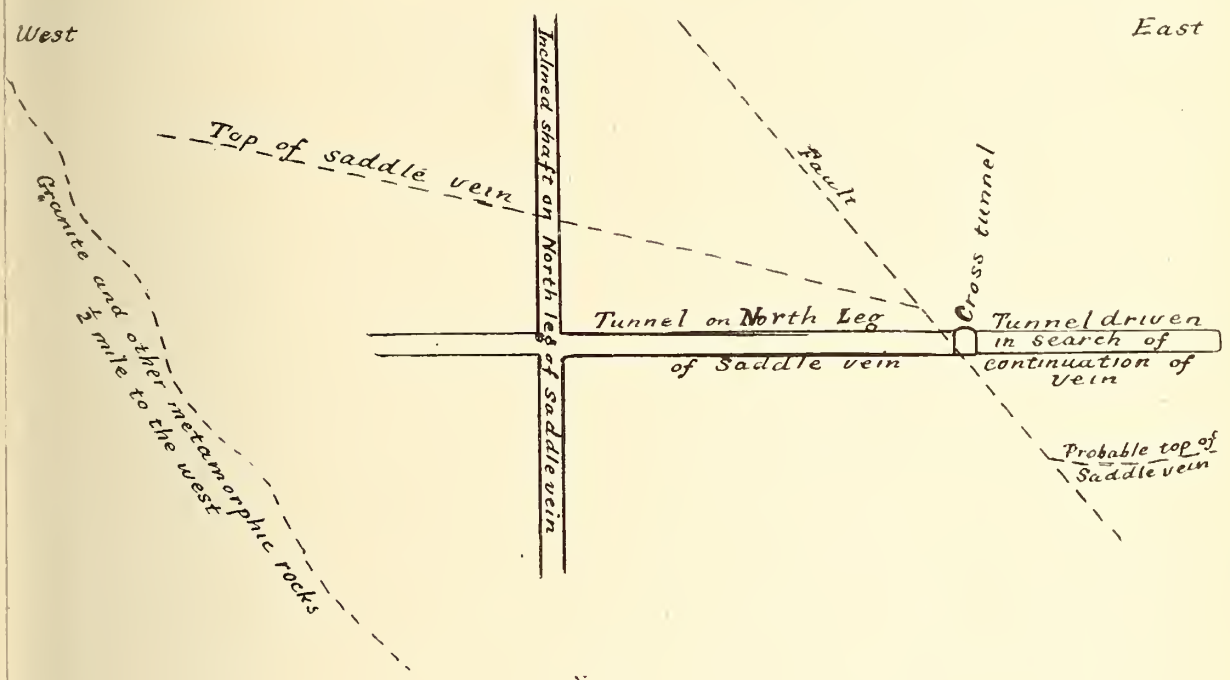
erground section in Mooseland, N.S.

e angles of dip and proportionate length of are only approximate, this sketeh will give a ea of a problem that eost the Mooseland Gold Company much money and disappointment. prospeetors despised geology, and the eastern on of the vein still remains unopened. The ting tunnel was first carried east along the of the antieline in the belief that the apex of ldle vein would be cut in its downward piteh to t. Failing in this, the tunnel was turned to the o ent the south leg of the vein. This plan also for the simple reason that the vein was not there.

Problems in Prospecting—No. 4.

Spectacle Lakes, Lunenburg Co., N.S., Surfaee plan.

About 20 years ago large gold bearing boulders were noticed along the west side of a valley near Spectacle and Dares Lakes, and considerable prospecting done; as usual, in a northerly direction. At a short distanee the boulders disappeared and no vein was found. About 15 years ago I found, about a quarter-mile further south, another deposit of float ore, and put down a couple of trenches parallel to the line of drift. Beeoming convinced that the vein ran north and south, I put the next trenches across the line of drift. Then, as an examination of the other deposit of float ore made it evident that both eame from the same vein, I transferred my operations to the long trench which



West

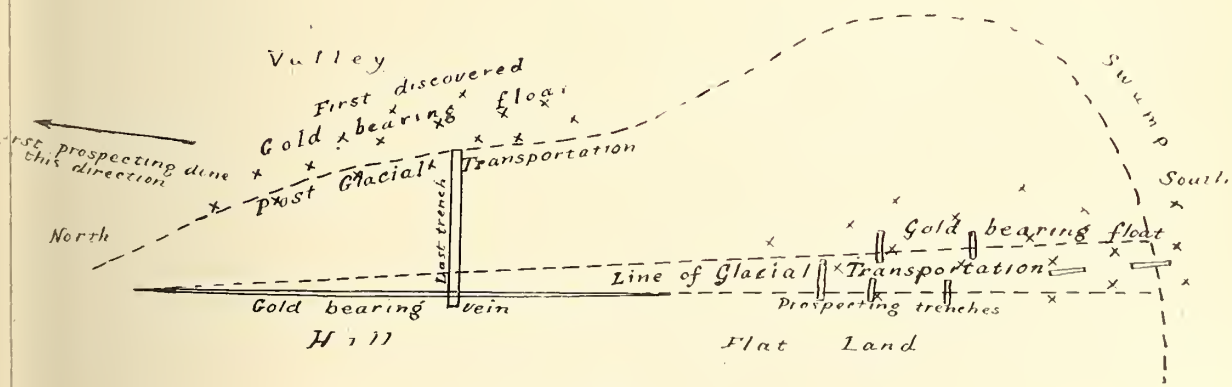
Fault
Cross tunnel
Granite and other metamorphic rocks ½ mile to the west
Tunnel on North Leg of Saddle vein
Tunnel driven in search of continuation of vein
Probable top of Saddle vein

No 3.



No. 4.

The evidenee available points to the following as the true explanation of the problem. Maintaining the metamorphic origin of the granite of Nova Seotia, this rock in eooling contraeted. This contraetion resulted in fault parallel to the boundary of the formerly molten mass. The western side of the fault being drawn toward the shrinking granite, left an opening into which the overhanging eastern side settled, thus bringing the higher strata on the eastern side opposite lower strata on the western side. The vertical displacement is still unknown.

crosses the vein. The deposit of float at the foot of the hill was evidently the result of erosion by subaerial influences in post-Glacial times. The discovery of the vein the next day, up the hillside and beneath only two feet of soil, eonfirmed my views. The general course of glaciation during the Glacial age was south a little east. Then eame the retreat of the eontinental iee sheet, while the province was still submerged; the deposition of the clays and sands which underlie the post-Glacial ore deposit here shown; then the deposit of the ore as mentioned in the valley east of the vein,

after the elevation of the land had made some progress. The action of frost, the flow of water, and the force of gravity, were ample causes for the transportation of ore from the higher to the lower level. This is a common occurrence in hilly countries, but is not often taken into consideration in this land of deep drift, where the finding of a vein so near the surface is a very unusual event. This problem is given as a sample of one of the simplest we have, but difficult only because we seldom expect it. However, there are in some of the eastern districts deposits of glacial debris modified by post-Glacial influences to a far less extent than in the above case, owing to the land being level, the surface deep, and brooks or lakes absent.

These few examples show the great variety of problems facing the prospector in Nova Scotia. Not only must he be a man of unlimited resource and skill in the manual work necessary, where money is doled out so sparingly as here, but he must be an adept the solving of riddles in structural and Glacial g ogy. With a proper training on lines indicated in th going article, I believe we would hear of fewe fa ures in prospecting. A revival of gold mining in Scotia should result from the finding of some long-hidden bonanzas, without reference to p known values. A prospectors' handbook, shorn f technical terms, and worded in the phraseology mucker, should find a ready sale here. Its use is pensable to the modern prospector in deep s yet I do not know that such a special work as t ever been published.

I shall close with the hope that the foregoin gestions and examples may be of use to some on like myself, has had to spend time and labour solving without instruction of the numerous pr facing the prospector.

OUR EUROPEAN LETTER

OUR EUROPEAN LETTER

South African mines a drug on the London market—Reasons Discussed — Reports of important properties — Tin and copper mining — Northern Nigeria and its tin pressing forward — Revival of Russian mining — An echo of the Whitaker Wright smash—British coal masters and thin seam mining.

(Exclusive correspondence to CANADIAN MINING JOURNAL.)

London, May 19th, 1911.

South African mining companies on the London and provincial Stock Exchanges continue to be so negligible that the monthly statements of the gold output and labour situation have very little influence. Certainly very good returns are almost without effect upon the market, though possibly if very bad ones came there would be an appreciable decline owing to the lack of support. The gold output for April shows a decrease compared with March of 8,351 ounces, but this is considered satisfactory seeing that March contained one working day more. It is pointed out, too, that the return represents a value of $1,033,660 in excess of that of April last year, and is a "record" for a 30-day month. The average daily yield for April from the Witwatersrand mines alone, 21,280 ounces, shows an increase on March of 337 ounces. The number of natives employed by mining companies forming the Witwatersrand Native Labour Association is higher now than ever before, and at 213,111 shows an increase of 11,000 on the month. This is the more satisfactory, having regard to the expected growing efficiency of the raw "boys" recruited during the past three or four months. In April last year the total number of natives employed was 206,680, and since then the figure has been below 195,000. The Rand, therefore, has not missed the Chinese coolies.

Many theories are propounded for the absence of public interest. It has been attributed to the operations of the "shops" who are accused of artificially raising or depressing shares under their control as it suited their books; to the surfeit of gambling in rubber and oil shares; to the Wernher-Beit Rand Mines "deal"; to what was thought to be the unfriendly attitude of the Union of South Africa Government in bringing forward adverse legislation; and to a condition of labour shortage resulting in higher working costs and smaller returns. With respect to th mentioned factor, a private telegram was re from Johannesburg on April 21st stating that monthly meeting of the Transvaal Chamber of the president expressed the opinion that by O 1st next there would be very few if any less employed on the mines than to-day.

The sixteenth annual report of the Rand Limited, a very important and bulky docume cludes a full report of the annual meeting h March last. At this the remarks of R. W Schu were of unusual interest. In view of the last returns, showing the employment of a larger n of "boys" on the Rand than ever before, it strange to read the Rand Mines' chairman's stat that scarcity of native labour does exist, and one serious cloud on the horizon. The natives n ing recruited are, he says, of inferior physiqu at all events, for the first few months, are not ve cient workers, while a great drawback has be exceedingly high death-rate among them. It is able, too, that with the increase of development more labourers than formerly are wanted. The dy in the opinion of Mr. Schumacher, is to trai white men for using machine drills. The grea gress made in mining by the more extended machine drills, the electrification of mine plant proved methods of handling ore, and the bett commodation of white and coloured employee opening up, he said, a new era in mining. A which created great interest in London, and for was a depressing market factor, was the purch shares from the Wernher-Beit group. In defe this the chairman pointed out that it is good poli the Rand Mines to acquire such important in and thereby extend the scope of their operations nine companies in which it is proposed that the Mines should acquire interests are all mines with areas, and of these the eight companies already have a grade above the average of the fields. chairman's speech treated the whole subject of mining most comprehensively, and a perusal would repay those interested.

The Barnato group of seven important Ran panies has just issued reports which compare vourably on the whole with 1909. Two concern

, but the remaining five have distinctly fallen The net profit of the Consolidated Langlaage as fallen from $520,000 to $170,000; The Ginsompany, from $265,000 to $190,000; the Glenompany, from $200,000 to 125,000; the Unified eef, from $185,000 to $85,000; and the New tein Estate, from a profit of $440,000 in sixteen to a loss of $295,000 in twelve months. With to the members of the group that have done the Witwatersrand Gold shows an increase of it from $480,000 to $825,000, and the New Primincrease from $785,000 to $940,000.

The mining of tin and copper is making rapid headay i the Transvaal and if anything like the same te c progress is maintained during the next few ears he base metals of the Transvaal may form the ions of industries which will be anyhow a very ood cond to the Rand both in volume and profit. Altho h it has been long known that there were deosits f tin ore in the Transvaal, they attracted very tt tention, and were not taken seriously until wh t known as the tin boom, which took place in 1905. n that year there were important finds of both m n copper, and two years later the output was ufficiet tly important to figure in the official returns. As regrds tin, the rapidity of the growth of the instry may be realized by noting that, while in 1905-6 he estnated value of the tin ore production was $22,-70. tl total produced up to the end of 1910 is reorded as $3,456,750. Up to date, it may be said that he ra e of the output is about $3,750,000, and fresh iscov ies are still coming along.

The reat bulk of the output of tin comes from the four cmpanies working on a considerable scale, each ompa y having a mill of ten stamps. The position of ffairs n the tin industry and the tin trade of the rest f the world is sufficiently interesting at the present me t give the Transvaal development in connection ith t metal a world-wide importance. The tin posiion gherally presents an economic prenomenon that as pehaps never had a precedent in the history of minera industry. Tin, notwithstanding the erratic luctuaions in price, has one of the steadiest and most ersist t of markets, so far as bona-fide sales for conumpt n are concerned.

As te population of the world increases and civiliation preads, the demand for tin becomes greater and ull g ater. Meantime, the supply of tin remains ractidly stationary. While the output of the metal s con antly being added to by new discoveries, the lder elds are being gradually exhausted, and, takng th world-wide result, there is so little change in he aggregate that it is difficult to see the probability f any considerable development in the future.

Whether copper-mining in the Transvaal will ever e of ery great relative importance is still, perhaps, t moot point. There is known to be south of the Limopo iver, near the Rhodesian boundary, a large ren i which copper exists, and one company at least s exploiting the deposits. At present there is a cerain dficulty with regard to transport, but the comany, hich is finding very rich ore, is sending it to Sando erkop, about 60 miles from the mines. The re ha been treated in Europe, and up to June of st yr the 7,000 tons odd which had been shipped re sal to average 54 per cent. of copper contents. This, f course, is extremely rich stuff, and it can hardly be expected to continue at the same high level f any great quantities. It is estimated that the averge would work out at about 12½ per cent.

Interested parties are still seizing every opportunity for bringing Northern Nigeria, and especially its tin resources, more and more before the British public. Sir Hesketh Bell, the Governor of Northern Nigeria, read a paper in London at a dinner on May 12th in which he remarked upon the successful administration of this African protectorate. On the question of transport, which so intimately affects the growing mining industry there, he said that the most important development of late consisted in the construction of the Baro-Kano Railway. This line, originally suggested by Sir Frederick Lugard and planned by Sir Percy Girouard, was practically completed only three weeks ago. It held a record for celerity of construction and economy of cost. Three years had hardly elapsed since the first sod was turned at Baro, and on the 8th of April the first train steamed into Kano, having travelled from Baro, 360 miles distant. Between Zaria and Kano no less than 6¼ miles of rails were laid in a single day. The cost would only very slightly exceed Sir Percy Girouard's original estimate of $15,000 per mile, and the line had the merit of being by far the cheapest railway ever constructed in tropical Africa. In a few weeks it would be possible to go from Lagos by way of Kano, nearly 800 miles from the coast, in little more than three days. Up to quite recently such a journey, even on horseback, could not have been done in less than a month.

Several new tin companies have been floated in London, but on the properties themselves nothing much can be done until the close of the wet season. Segar R. Bastard, a solicitor by profession, is perhaps the best known figure behind the Nigeria tin movement in London. A contemporary of the present Premier at the City of London School, he was one of the earliest financiers and promoters who interested themselves in Northern Nigeria. It was owing to his enterprise that the Champion Gold Reefs of West Africa, a gold mine which had practically floundered, sold up its remaining assets and invested the last of its money two or three years ago in the then untried Northern Nigerian tin fields to such a good extent that within the first year a hundred per cent. dividend was paid. The company, now known as the Champion Tin Mines of Northern Nigeria, is now the parent of half a dozen of the most important alluvial tin propositions out there.

An interesting revival is taking place in the English capitalized mines of Russia. Prices of the leading dozen companies have risen substantially in the last month and Lena Goldfields have received special attention. Very many of the deals here are on behalf of people in St. Petersburg, who have taken up one share after another. This Russian group, so far as London is concerned, has been in such a moribund condition since the sensational collapse of about four years ago that even now it would not be overstating to say that dealers generally are completely bewildered at this unexpected turn of events. In the meantime, a demand is proceeding on Continental account which literally takes one's breath away, having regard to the heavy lines of stock which are daily changing hands.

One of the biggest achievements and greatest gambles of the Whitaker Wright regime is recalled by the announcement of a reconstitution scheme for Lake View Consols. The scheme is explained in a circular from the directors, and it is proposed to form a new company with a capital of $875,000 in ten shilling ($2.50) shares, one of which will be given in exchange for each

five-dollar share in the existing company. Formed in 1896 under the auspices of the notorious London and Globe Finance Corporation, Lake View Consols acquired the Kalgoorlie properties known as the Lake View and Boulder East from a colonial company for $1,100,000 in fully-paid shares. The quotation of the shares was soon soaring to great heights. In October, 1897, an interim dividend of $2.50 a share was paid, and the five-dollar shares reached $63⅛. A further $2.50 was paid in April, 1898. In 1899, $12.50 per share, or 250 per cent., was paid, and the quotation reached its record mark of $144⅜. The wild fluctuations of the shares can be gathered from the fact that in the same year the price dipped to $45 15-16. In 1900, during which $6.25 a share was paid, the highest price was $76⅞. At the end of that year came the great Whitaker Wright crash, and on December 28, 1900, the shares were cut down by one fell stroke from $65 to $38¾. In the following year 50 per cent. was paid in dividends, but since then the distributions have amounted in all to no more than $1.60 a share. The quotation reached its low record of $1.50 in 1908. Now it is $3.56.

British coal masters are being driven to a rapid improvement of their methods by the fact that the days of plenty of coal are drawing to an end in this country as they must do with an annual output of 264,000,000 tons. Coal owners are being forced to open up extremely thin seams, and at the present time seams of coal is being worked in Lanarkshire which is only 14 inches in thickness. To enable the collier to get at the coal it is "undercut" 5 inches, and so the collier is favoured with a space 19 inches wide, in which he has to spend about seven hours per day. To get to his "place" he wriggles, or one may say swims, some yards.

It will be realized that the cost of "getting" coal from a thin seam must be very much greater per ton than from a thick seam, and the problem which the colliery manager faces is how to reduce this cost. The result of studying this subject was, first, the coal cutter and, as a natural complement, the face conveyor. This problem of the coal cutter is largely one of compact and strong gearing, and it will be evident how far this problem is from a satisfactory solution when it is stated that a machine costing, say, $1,000, may easily take $500 per annum to keep it in repair. It must be remembered, of course, that a collier is no machine and that from him machines need expect no gentle handling and very little sympathetic treatment.

THE VOLUMETRIC ESTIMATION OF SULPHUR IN IRON AND STEEL.

By T. GIFFORD ELLIOT (Sheffield).

(Paper read before the Iron and Steel Institute.)

The methods used in the analysis of iron and steel twenty years ago were largely gravimetric, whereas the majority of those in use at the present time — at least in a works laboratory — are volumetric, although in the estimation of sulphur in iron and steel no volumetric process has yet been discovered which is universally applicable, and the gravimetric process known as the "aqua regia" is still in constant use.

Whether the "aqua regia" or Bamber's method be used, the gravimetric estimation of sulphur is very tedious, and liable to error even in skilful hands. This is proved by the difficulty of obtaining results in agreement from different laboratories on the same sample, although variations in the method of working are probably responsible for some of the discrepancies.

The volumetric estimation of sulphur has received considerable attention during the last few years, and many papers have been written on the subject. Most of the work has been devoted to eliminating the loss of sulphur in the evolution method, generally thought to be due to the formation of organic sulphur compounds instead of sulphuretted hydrogen, on attacking the metal with acid.

Various suggestions have been made with a view to effecting this most necessary result. The chief are as follows :(1) The speed of solution should be as quick as possible. (2) The gases from the evolution flask should be passed through a hot tube to decompose any organic sulphur compounds, and then into an absorption flask. (3) The weighed portion of the sample should be annealed in a non-oxidizing atmosphere before treatment with acid. (4) The acid used to dissolve the metal should be concentrated hydrochloric acid of 1.19 specific gravity.

Schulte[1] and also Phillips[2] in 1895 suggested passing the gases through a red-hot tube.

In 1902 Walters and Miller[3] first suggested the annealing of the weighed portion for analysis before treatment in the evolution flask. They placed the sample in a porcelain boat and heated to bright redness in a tube in a current of hydrogen for fifteen minutes, if the sample contained an "appreciable amount of titanium," for half an hour.

In the same year Dougherty[4] made the annealing more practicable, by suggesting the use of a covered porcelain crucible for the purpose, with a piece of filter paper placed on the drillings to provide the non-oxidizing atmosphere.

C. A. Seyler[5] described his experiences with Dougherty's method, in a paper read before the Society of Public Analysts in December, 1902. He obtained the best results by annealing at 750 deg. C., although he stated that more experiments were required to determine the best temperature. So far as I am aware, this is the only published instance where the temperature of annealing was measured.

S. S. Knight[6] modified Dougherty's method in 1906 by mixing the sample with pure iron dust reduced in hydrogen. The mixture was placed in a porcelain crucible, covered with a little more iron dust and a piece of filter paper. The lid was put on, and the crucible heated for ten minutes "at the highest heat obtainable by a blast lamp."

In 1906, J. MacFarlane and A. W. Gregory[7] suggested the use of cream of tartar to mix with the drillings for annealing. They mixed 5 grammes of the powdered sample with half a gramme of cream of tartar, wrapped the drillings in filter paper, placed in a small porcelain

le, covered, and annealed at a bright red heat in le for fifteen minutes.

interesting report was presented in 1908 by H. r,[8] of the work of a chemical commission appoint- the German Society of Ironworkers, to inquire he estimation of sulphur in iron and steel. The gur obtained show that the highest results were got e use of strong hydrochloric acid, 1.19 specific ravy, and quick evolution, and that under these con- tio the use of a red-hot tube is unnecessary.

In laboratory where the ordinary routine consists analysis of samples varying from the best hæ- iron to high phosphorus foundry iron, and from rest transformer iron through the many varieties l used for steel castings to complex alloy steels, plicability of a method for general use is severely te

I ve found that many samples of iron and steel do not olve their full sulphur contents after merely an- lig in a non-oxidizing atmosphere, when treated with oncentrated hydrochloric acid. MacFarlane and Gregory's method of annealing with cream of tartar, ho er, gave me excellent results with some brands of iron ith which I had previously not succeeded; but with ther brands, and particularly with nickel-chrom- um eels and other self-hardening material for which I wa very anxious to find a quick method of determin- ng te sulphur, the full amount was not obtained. I am n t overlooking the fact that the method was only desig ed for irons.

My experience agrees with the finding of the German mission as to the importance of using concentrated acid nd rapid evolution. Moreover, in many experi- ment I passed the gases from the absorption flask throu h a red-hot tube and into a second flask, but the a ount of sulphide obtained in the second solution was gligible.

In rder to find a more active reagent than cream of tarta I tried various substances, and finally chose pota sium ferrocyanide. The effect of heat upon this subst nce is to decompose it into carbide of iron, potas- ium yanide, and nitrogen. The result is, that the drill gs are more or less carbonized, and a strongly reduc g atmosphere obtained.

Ex riments made to determine the length of time requi d for annealing, indicated that with less than went minutes, low results are obtained. On the other hand, no advantage is usually to be gained by ex eeding this period, whilst in the case of steel drill- ngs, xidation is then liable to occur.

An aling experiments with different amounts of ferro yanide indicated that 0.25 gramme mixed with 5 gra mes of the sample, was the most suitable amount. If m e is used, cyanogen compounds may be driven into e absorption flask, especially if the condensing tube ets hot. The result is, that when the titration is ma e by adding iodine to the contents of the ab- sorpt n flask without filtering, acidified only with acet ic acid, an excess of iodine may be added beyond that equired to dissolve the sulphide, without any colou being imparted to the solution. (A drop of stare solution added here gives the characteristic blue colou) On adding dilute hydrochloric acid, the brown colou due to the excess of iodine appears, and the tit- ration is proceeded with as usual, the result being un- affect d, notwithstanding.

Ex rience has shown that in order to obtain correct result it is absolutely necessary to control the tem- pera e of annealing. As will be seen from the table of results the correct temperature lies between 750 deg. C. and 850 deg. C.

If there are no means of measuring the temperature available, it is necessary to work a standard of known sulphur content with each batch of samples annealed.

An indication as to whether the sulphur is being evolved correctly is furnished by the colour of the precipitated cadmium sulphide. This should be distinctly yellow. A pale precipitate is usually associated with a low result, and suggests that the annealing has not been conducted properly.

In order to promote uniformity in the rate of solution, which is important, it is advisable that the drillings of the sample should be of the same degree of fineness as the standard, and of similar composition. Reference is made below to the use of a standard.

The method I have adopted is as follows: 5 grammes of the sample are mixed, as far as is practicable, with 0.25 gramme of pure finely powdered anhydrous potassium ferro-cyanide, and wrapped in one 9-centimetre filter paper if the sample is a graphitic iron, or two papers if it is a steel or white iron, placed in a small porcelain crucible (Royal Berlin O.A.), covered with the lid, and annealed at 750 deg. C. to 850 deg. C for twenty minutes in a closed muffle. After the annealing and subsequent slow cooling outside the muffle, the drillings should still be covered practically completely by the charred filter paper, if the temperature has not been above 850 deg. C. or they have not been in the muffle too long. I make a point of observing the appearance of the annealed drillings very closely, because low results are obtained if the paper is completely burnt away from the top of them. After cooling, the crucible is emptied into a glass mortar, and the slightly caked drillings loosened with a pestle. They are then brushed on to a small piece of stiff paper, which is rolled into cylindrical shape so that it will fit right into the neck of the evolution flask, and allow of the drillings being transferred to the flask without touching its neck or sides. The evolution flask is connected with a condensing tube 6 inches by 1 inch, containing about 2 inches of water, and standing in a conical beaker filled with cold water. A tube from this dips into a flask containing 60 cubic centimetres of the cadmium chloride solution, which again is connected with another flask containing more cadmium solution. Fifty cubic centimetres of concentrated hydrochloric acid are now added, and heat is immediately applied to the flask until the frothing of the contents indicates that the solution is well in progress. The flame of the burner used to heat the flask is lowered. As soon as the speed of the bubbles of gas passing through the cadmium solution begins to slacken, the flame of the burner is raised so that the liquid in the flask just boils. The boiling is continued so long as any appreciable amount of gas is given off from the solution. The apparatus is then disconnected, and iodine solution added in excess to the contents of the absorption flask — usually nothing is found in the safety flask; then 10 cubic centimetres or so of diluted hydrochloric acid (one part acid and two parts water) are added, and the liquid shaken to complete the solution of the sulphide. The excess of iodine is then titrated with sodium thiosulphate, starch solution being added when the iodine colour has nearly disappeared. (The air in the apparatus may be washed out by carbonic acid before the addition of the acid to commence with, and again at the end of solution of the drillings, if desired, though

the slight advantage gained thereby is hardly worth the extra trouble for works practice.)

If the filter paper used to wrap the drillings, or the ferro-cyanide itself, contains sulphates, the latter are reduced during the annealing, and their sulphur given off as sulphuretted hydrogen in the evolution flask, so that a blank determination becomes necessary. The blank can be conveniently determined upon a pure iron, by dissolving 5 grammes of the iron in concentrated hydrochloric acid, and absorbing the sulphuretted hydrogen as usual. By annealing another 5 grammes of the iron in the usual way, and determining the sulphur contents as in the direct estimation, any difference due to the above causes can be determined.

The iodine and thiosulphate solutions may be standardized by means of a steel or iron, the sulphur contents of which have been accurately determined by the "aqua regia" or Bamber's method. The value of the solutions in sulphur so obtained, should agree closely with that got by calculation after standardizing the thiosulphate against a standard solution of potassium permanganate. The latter is very easily performed, and is a very useful check on the working of the process. The solutions of iodine and thiosulphate used are of such strength, that 1 cubic centimetre equals 0.005 per cent. sulphur on 5 grammes of the example.

The cadmium chloride solution is prepared by dissolving 20 grammes of cadmium chloride in water with the aid of a few drops of hydrochloric acid. Ammonia is added until the precipitate of cadmium hydrate formed, completely dissolves. Acetic acid is then added until the solution becomes slightly acid, when a further 20 cubic centimetres are added in excess, and the solution made up to 2 litres.

I find the cadmium solution acidified with acetic acid, and containing ammonium acetate, the best absorbent to use. It does not absorb the hydrocarbons, phosphides, etc., simultaneously evolved with the sulphur compounds, to the extent that solutions of salts of zinc, lead, and copper do, or as do the alkaline solutions frequently used for this purpose. I have frequently tested the point by filtering off the cadmium sulphide before titration, and comparing the results obtained by titrating the washed sulphide, with those got by direct titration.

The three steels each contain over 1 per cent. of both nickel and chromium. No. 8620 is in the cast condition, R. 4290 in the tempered, and No. 8672 in the annealed state. The latter contained under 0.05 per cent. of hardening carbon, and practically the whole of the sulphur was obtained as cadmium sulphide by direct evolution. This is most important, and I believe that therein lies the solution of the problem of how to obtain the whole of the sulphur in a sample of iron or evolved as sulphuretted hydrogen by hydroch acid. It is, of course, absolutely necessary that sample should be completely decomposed by the In the case of irons containing titanium, as Blair shown, this is not the case, and some of the sul may remain in the evolution flask in the inso residue. I have experimented with an iron contai 0.2 per cent. of titanium. The sulphur content tained by a gravimetric method which included fusion of the insoluble graphitic residue after t ment with aqua regia, was 0.080 per cent. The d evolution gave 0.017 and 0.018 per cent. After an ing at 800 deg. C. the amount obtained was 0.06 cent. The special treatment (referred to in the column of results in the table) consisted in placing crucible containing the sample in the muffle at 950 C., and leaving at that temperature for five min The gas was then turned off, and the muffle allow cool down to just below 800 deg. C. The gas was relighted, and the temperature of the muffle ke about 790 deg. C. for fifteen minutes. The cru was then brought out to the front of the muffle allowed to cool slowly. The sample containing t ium after this treatment gave 0.076 per cent., w suggests that by a proper preliminary treatmen whole of the sulphur may be obtained even fron iron containing titanium by the evolution process

Iron No. 471 was found to give off the whole sulphur as sulphuretted hydrogen by direct evol (i.e., without any preliminary treatment).

As it is my custom to have all iron samples ann before treatment in the evolution flask, I experim with this sample in order to test the effect of th nealing on the amount of sulphur obtained. The re are given in the table.

I wish to express my thanks to Messrs. G. B. W A.R.S.M., and E. G. Barnes (the latter of whon been responsible for the control of the annealing whom I am indebted for the carrying out of a amount of the experimental work involved in the paration of this paper.

Canadian Mining Institute—Western Branch.

The tenth general meeting of the Western Branch of the Canadian Mining Institute was held at Trail, British Columbia, on May 18. Mr. Wm. Fleet Robertson, provincial mineralogist, chairman of the branch, presided, and there was an attendance of members and visitors from various parts of the Kootenay and Boundary districts, the neighbouring State of Washington, and the coast cities, Victoria and Vancouver. There were two sessions—afternoon and evening.

The visitors were welcomed by the president of the Trail Board of Trade, after which several papers were read and discussed. These were: "The Burns Anthracite Coal Property, Alberta," by Mr. Alexander Sharp, M.E., Orient, Washington; "Costs of Operation at the Rambler Bell Mine, Kootenay Lake, B.C.," by Mr. S. S. Fowler, M.E., Riondell, B.C.; "Notes on Property of the Le Roi No. 2, Limited, at Rossland, B.C.," by Mr. Ernest Levy, M.E.; "The Standard Mine, Silverton, B.C." by Mr. John Valance; and (by title only) "Notes on the Lucky Jim Zinc Mine, Slocan, B.C.," by Mr. A. J. Becker; "The British Columbia Copper Company's Smeltery, Greenwood, B.C."; "The Van-Roi Mining Company's Concentrating Mill, Four-mile Creek, Slocan," and a description of the copper smelting side of the Consolidated Mining and Smelting Company's smeltery at Trail.

Mr. H. Mortimer-Lamb, secretary of the Institute, who had journeyed from Montreal, Quebec, to British Columbia to attend the meeting, read a letter of greeting from Dr. F. D. Adams, president of the Institute, and explained the proposal of the council of the Institute to hold a semi-annual meeting in British Columbia in the autumn of each year, this to be as far as practicable similar to the general meeting of members held annually in one of the cities of Quebec or Ontario. It was recommended that the first of these proposed semi-annual meetings shall be held next autumn. The matter was referred to the incoming branch council with a recommendation that it further the efforts of the general council to make such semi-annual meeting a success.

An invitation to hold the next general meeting of the branch (in September) at New Denver, Slocan Lake, in the vicinity of which town several important silver-lead mines and concentrating mills are being operated, was favourably received and referred to the branch council for its decision thereon.

A proposal that the Provincial Government be urged to either add to the staff of the Provincial Bureau of Mines, or employ mining engineers not on the staff, to do exploratory work in new districts in the province giving promise of becoming mining fields, was not adopted, it being considered that the meeting was not in possession of sufficient information to show that there exists a public demand for such action, or other reasons that would warrant its making such a recommendation to the Government.

The result of the ballot for chairman and members of the branch council for the ensuing year was that Mr. Robert R. Hedley, of Vancouver, B.C., was unanimously elected chairman, while all but one of the twelve elective members of the branch council were re-elected, the only new member being M. E. Purcell, superintendent of the Centre Star group of mines, Rossland, B.C. The Branch officers and council for the ensuing year are as follows: Chairman, Robert R. Hedley, Vancouver, B.C.; Secretary, E. Jacobs, Victoria, B.C.: Council—W. H. Armstrong, Vancouver, B.C.; *S. G. Blaylock, Moyie, B.C.; S. S. Fowler, Riondel, B.C.; Norman Fraser, Michel, B.C.; Chas. Graham, Middlesboro, B.C.; Thos. Graham, Nanaimo, B.C.; J. Cleveland Haas, Spokane, Wash.; John Hopp, Barkerville, B.C.; W. H. Trewartha-James, Victoria, B.C.; *Frederic Keffer, Greenwood, B.C.; *Thos. Kiddie, Vancouver, B.C.; F. C. Merry, Ferguson, B.C.; M. E. Purcell, Rossland, B.C.; *W. F. Robertson, Victoria, B.C.; Lewis Stockett, Hosmer, B.C.; *O. E. S. Whiteside, Coleman, Alberta; W. E. Zwicky, Kaslo, B.C. Mr. Hedley presided during the latter part of the evening session.

On Friday morning, May 19, some of the visitors were shown through the Consolidated Mining and Smelting Company's copper and lead smelting works and electrolytic lead refinery at Trail, and in the afternoon spent several hours in the company's Centre Star mines, at Rossland.

The Burns Anthracite Coal Property, Alberta.

Mr. Sharp showed that this property consists of 15,360 acres of Crown-granted land, beside an area leased from the Dominion Government. The nearest railway towns are Calgary and Okotoks, each distant about 45 miles from the property. The coal measures belong to the Lower Cretaceous period (Kootenay series). The formation comprises about 4,000 feet of sandstone, dark shale, conglomerates, and—near the base—some clay and ironstone. At intervals in the strata occur the coal seams and coaly shales, the whole resting on carboniferous lime. The area is 11 miles long and from one mile to three miles broad. The measures lie in a long, narrow, synclinal trough; strike N. 42 deg. W., and dipping to westward at an angle varying from 52 to 80 degrees. The southeastern outcrops are at elevations from 300 to 2,000 feet above the valley of Sheep Creek, but towards the north, at Burns Creek, the coal comes down to the level of the valley and has every indication of going deeper. Ten or twelve seams of coal have been exposed and traced, by drifts and open-cuts, about five miles. These exposures show fully 100 feet of coal in the measures. Fifteen samples, taken from seams ranging from 4 feet 6 inches to 20 feet in thickness, gave analyses varying between the following percentages: Moisture, 1 at 2.10 per cent.; fixed carbon, 70.05 at 82.25 per cent.; ash, 3.5 at 17 per cent.; sulphur, 0 at 1 per cent.; volatile, 9.6 at 13.43 per cent.; B.t.u. (one sample), 14.877. Complete analyses of two samples from a 7-foot seam on Rickert Creek were as under:

Water, 0.98, 1.02; carbon, 84.77, 87.24; ash, 5.42, 5.92; sulphur, 0.18, 0.18; hydrogen, 3.63, 2.92; oxygen and nitrogen, 4.48, 3.24, coke, 90.64, 92.81.

The topography of the country is favourable to economical mining. Some of the seams come down to the level of the valley, so can easily be reached by tunnels at the valley floor. Any of the seams can be drifted on from either side of the several creeks that cut the formation. Thus a chain of collieries can be operated along the valley Power can be generated from water power of the creeks. The seams are being prospected at different horizons so that the nature of the roof and floor texture may be ascertained before any permanent opening shall be made. The difference in elevation between the coal property and Okotoks is about 2,150 feet, or approximately 48 feet to the mile

*Members of Council ex-officio.

Costs at the Blue Bell Mine, Kootenay Lake, B.C.

Mr. Fowler, who will later prepare his paper in fuller detail, made an appeal for voluntary publication of costs of operation of mines or dressing plants, stated in connection with all the conditions which control those costs. The object of obtaining these would be to afford means whereby those to whom the figuring should become accessible might more accurately forecast the results of new undertakings. In order to set an example Mr. Fowler presented figures of costs pertaining to the operation of the Blue Bell mine and ore-dressing plant, including all overhead charges except interest and sinking fund. A summary of the figures presented shows that in the treatment of 43,069 tons of ore (containing lead, iron, and zinc) during nine months prior to March 31, 1910, the cost of ore extraction was 98.4 cents; concentration, including weighing of ore and loading of product, 50.2 cents; and management and all general expenses, 37,6 cents; total, $1.862 per ton. These costs were attainable only through the means of extraordinarily favourable physical conditions, but the result was also much assisted by the loyal co-operation of staff and mine and mill crew.

Property of Le Roi No. 2, Ltd., Rossland, B. C.

This property comprises more than 150 acres, situated in the vicinity of the mining groups of the Consolidated Mining and Smelting Company of Canada, Ltd., and the Le Roi Mining Company, Ltd., Rossland, B.C. It has been investigated by two mines—Josie and No. 1—and by numerous surface workings. Several veins have been worked. The country is much broken and displaced by numerous dikes, and the solution of the problem as to what is the result of these disturbances is still unfolded. The most important dike is that known as the Josie, which has an average width of 100 feet, striking approximately north and south and dipping 84 degrees to the west. Corresponding figures for the Tramway dike are: Width, 50 feet; strike, N. 20 deg. E., and dip 70 deg. E. Both are accountable for surface depressions, due to their adaptability to more rapid erosion. The minor dikes strike roughly parallel with the Josie, with dips, as a rule, not far from vertical. The main rock disclosed by the workings is the augite porphyrite which varies considerably in texture, hardness, and breaking qualities in different parts of the mines. The orebodies are erratic, both as to position and variability in size, as well as disposition of value; additional difficulty is experienced owing to the visible characteristics of the ore seldom indicating its value at all, and this involves constant recourse to assaying. The orebodies vary in width from a knife-edge to 30 feet, so that there have been called for both the square-set and "shrinkage" stoping methods of ore extraction. The latter system is exercised to as great an extent as practicable on account of its smaller cost. By far the larger proportion of past production has been derived from between the 300 and 700-foot levels of the Josie mine.

The Josie main shaft inclines at 74 deg., has three compartments, and extends to the 1,300-foot level. It is 14 feet 6 inches by 5 feet inside the timbers, and is equipped with a 150- h.p. double conical-drum hoist. In the shaft building are grizzlies, 4 inch and 1 inch spaces, on which hand-sorting of ore takes place. The ore is separated into first-class, second-class, and mill ore. First-class fines is shipped to the smeltery, and the remainder sorted into shipping and mill ore, and waste; second-class fines is sent to the mill, and the remainder distributed as in the case of first-class. M ore is trammed direct to the concentrator. No. mine shaft is 3-compartment, 800 feet deep, and equipped, similarly to the Josie, with hoisting eng and sorting floors.

Figures covering the operations of the last fin cial year will serve to give an idea of what is acc plished by hand-sorting. They are:

	Tons extracted.
First-class ore	42,770
Second-class ore	5,790
Mill ore	4,480
	=53,040 to

which by sorting was resolved into:—

	Tons.
Shipping ore	29,776
Mill ore	17,553
Waste	5,711
	=53,040 to

Stoping costs were:—

Ore production: labour	$0.76
Explosives	0.32
Illuminants	0.03
Sundries	0.04
	—$1
Ore sorting labour	0
General expense	0
Power plant: labour	0.07
Supplies	0.36
	— 0
Mine general: Labour	0.33
Supplies	0.07
	— 0
	—
	$2

Average assay value of ore shipped was: Gold, 0.8 ounces; silver, 0.8086 ounces; copper, 1.6305 per c

During the last financial year there was done: D ing and cross-cutting, 4,202 feet; raising and winz 160 feet; total, 4,362 feet. Cost per foot, $17.72. was exceptionally high, however, due to greater de of working (chiefly on 1,300-foot level), bad pow and several other unusual conditions. The follow comparative table will show corresponding costs several consecutive years:

Year to Sept. 30.	Drifting and cross-cutting. Feet.	Raising and winzing. Feet.	Total Footage. Feet.	Total per f
1910	4,202	160	4,362	$1
1909	3,220	338	3,558	1
1908	4,302	270	4,572	1
1907	2,538	255	2,793	1
1906	3,392	187	3,579	1

In addition to the work done in 1910, as shown ab the main shaft was deepened 193 feet, at a cos $1.73 per foot, and 11,508 feet of diamond drilling done at $1.73 per foot. The average depth of dri hole was 371 feet.

The concentrator is capable of milling and trea 60 tons of ore per diem. The machinery is electric driven by motors aggregating 100 h.p.; it compr one 9 by 16-inch and two 8 by 12-inch Blake crush two 6-foot Chilean mills, and four Wilfley tables.

During the last financial year the grade of ore tr ed, and results, were: Mill feed, 17,235 tons; a value, gold 0.122 ounces and silver 0.255 ounces ton, and copper 0.554 per cent. Concentrate prod totalled 1,368 tons, assaying gold 1.297 ounces and

0.748 ounces per ton, and copper 1.144 per cent. per ton crushed was $0.99.

s a result of the company's mining and milling operations in Rossland during the financial year ended September 30, 1910, the net profit was $249,255.81.

Standard Mine, Silverton, B.C.

r. Vallance gave a comprehensive description of this property, which has attracted much notice of late owing to the opening in it of large shoots of ore containing much galena of good grade.

The group includes 13 mineral claims. The mine is at an altitude of 3,354 feet above sea level and 1,594 feet above Silverton, on the eastern shore of Slocan Lake, and distant from the mine one mile and a half. Development work on a systematic plan has been in practically continuous progress since 1904. The "big ore shoot" was cut by the lower levels in 1909-10, and the present remarkable showings of ore exposed.

The enclosing country consists of old and very siliceous sedimentary rocks, cut in places by masses and dikes of an eruptive rock generally classed as granodiorite. A large "boss" of this rock occurs along the east side of the Standard claim and is, apparently, the centre from which the local dikes radiate. The sedimentary strata is mainly hard, blocky argillites, siliceous shales, and impure quartzites. The Standard vein is a strong fissure cutting the Bedding planes of the enclosing sedimentary rocks; a dike of quartz-diorite-porphyry is intruded into the fissure and lies along the footwall side. This dike rock is much altered and appears to in some manner be closely connected with the principal orebodies found in the veins; probably the clayey-talcose matter of the altered dike has influenced the course of the mineral-bearing solutions and caused the ore to be deposited on or near the dike, where it is most frequently found. Much evidence of large and repeated movements is found in the vein, especially toward the hanging wall side, and, at some points movements have occurred after the formation of the orebodies—masses of galena being found deeply striated by movement of adjoining hard gangue material.

The principal minerals are argentiferous galena and zinc blende, with some pyrite, chalcopyrite, and grey copper (Freibergite) as associated minerals. The Freibergite occurs as speeks and bunches mixed with the galena, mostly, but occasionally with the blende, and it is evidently highly argentiferous for specimens have assayed as high as 2,000 ounces silver per ton. The vein gangue is quartz, lime spar, and spathic iron, with enclosed fragments of shale and occasional masses of altered dike rock.

In the workings above the fourth level, the orebodies were found lenticular in form and following a zone pitching about 30 degrees. From No. 4 down to No. 5 level the big shoot of galena has a pitch nearly 28 deg. Where the big shoot is cut by No. 5 level the vein gradually widens from 4 to 30 feet. Here the clean galena has its maximum width of 15 feet, the remaining 15 feet being high-grade milling ore with included masses of clean galena. From here to the present face of No. 5, which is approximately 1,200 feet from the portal of the adit, the vein widens and the orebody gradually changes its character, the shoot of clean ore giving place to a great mass of milling ore enclosing irregular bodies of solid galena. The ore shoot has been opened a length of 250 feet; a cross-cut at the present face shows ore, chiefly milling grade, about 85 feet in width.

The mine workings consist of six levels. with connecting raises from No. 5 upward, and a number of cross-cuts from the levels, where the vein is wide. Not including stopes and cross-cuts, the mine openings have, together, a length of 8,500 feet. The depth on the vein, from No. 1 to No. 6 level, is 740 feet. After connection shall be made with No. 5 raise, No. 6 will become the main adit for the mine, and the upper terminal of the aerial tramway will be placed at its portal.

Ore from stopes above No. 4 level was taken out by ordinary overhand method, and the ground timbered with a two-piece set, or by stulls, as required. In the lower levels, where the vein is wider, the large orebody will be extracted by overhand stopes, with square-set timbering. Ore extracted has been roughly graded in the workings; the cleaner ore has been sent to the sorting houses, while the cobbings from this, and all second-grade ore from the mine, have been placed on the milling ore dumps. Shipments to the smeltery to date aggregate 4,418 tons; average metal contents were: Silver, 78.46 ounces per ton; lead, 62.5 per cent.; zinc, 5.88 per cent. Some shipments returned more than 100 ounces silver per ton, and others 73 per cent. lead. In addition to large orebodies blocked out in the mine, there is much ore in the sorting houses ready for shipment when the aerial tramway shall be completed, while the quantity on the milling dumps is estimated at 8,000 tons, which will concentrate 3½ or 4 tons into one ton of shipping product.

Preparatory to mining on a larger scale than in the past, and commencing milling operations, a 10-drill compressor plant and a concentrating mill with a grinding capacity of 200 tons and dressing facilities for 100 tons per diem, are being put in. Water power will be utilized, with a head of 160 feet at the compressor and 275 feet at the mill. The Leschen aerial tramway will be 7,900 feet in length, with a grade of 16 per cent., and a carrying capacity of 20 tons per hour. The tramway and compressor should be in operation in July and the mill in October next.

Efforts are being made to organize a mining school in Nelson, B.C. A provincial grant is asked for, and the school will be in affiliation with the local high school.

One of the most enterprising mine owners of Slocan district, British Columbia, is Mr. Alex Smith, formerly of Toronto. For years he and a partner have been engaged in developing the Surprise mine, situated on the mountain divide between Cody Creek and McGuigan Basin, Slocan. After having sunk to a depth of 300 feet and taken out a considerable quantity of ore, the work of driving a long deep-level adit was undertaken. Several years' work resulted in the face of this tunnel reaching a point under the old workings of the mine, from which a raise was commenced. The distance to be raised was nearly 800 feet, and of this about 600 feet has been accomplished. The work with only hand drills and the ventilation not being good, progress has been slow, but there is now only 170 feet required to be raised to make the intended connection.

COAL-DUST EXPLOSIONS

(Abstract of Miners' Circular No. 3, U. S. Bureau of Mines.)

By George S. Rice.

(Continued from last issue.)

Moistening the Air Current.

The simplest method of keeping a mine damp is to put moisture into the ventilating current; then the air going through the mine does not dry the dust but carries moisture to it. There are two ways of putting moisture into mine air. One is by using fixed sprays of water placed at intervals through the mine; the other is by moistening the intake air at the mouth of the mine.

Water Sprays.

Water sprinklers should give a fine spray, as much like fog as possible, so that the water will be carried along by the air until it is absorbed as invisible vapor. The chief care needed in using sprays is to keep the nozzles from clogging and to prevent men and boys who do not understand the necessity for spraying, from damaging the sprays or turning them off to avoid getting wet in passing by.

Clean water should be used for spraying. The nozzles should be of the form least liable to clog and most easily and quickly cleaned after clogging. All nozzles should be inspected at frequent intervals.

There can be no question of the value of water sprays for laying dust. However, to get the best results from their use some mine official must be made responsible for the condition of the sprays at all times. He must also be required to see that there are sprays enough running to keep the relative humidity of the air currents at, or above, 90 per cent. In zero weather the incoming air may traverse 2,000 to 3,000 feet of entry before its temperature rises above the freezing point. Therefore at mines in districts where the winters are cold, provision must be made for draining pipes and nozzles throughout the intake part liable to freeze; and in cold weather the area must be wet down by hose or by water cars, so that it does not become dry. A recent dust explosion started in the haulage road, which was also the intake, at a point only 600 feet from the mouth of the mine.

Heating the Air and Using Water Sprays.

At certain mines the experiment is being made of heating the ventilating current at the intake to mine temperature and then moistening it by water sprays. This requires a somewhat costly heating plant, for in zero weather the warming of 100,000 cubic feet, more or less, of air per minute takes much heat. This method will moisten the mine air, but it is more expensive and complicated than the following method.

Steam Jets.

Under some conditions the easiest way of moistening the air current entering the mine is to use exhaust steam. The heat of the steam warms the intake air a little, and the moisture is supplied as vapor and in finely divided form, like fog. Generally the exhaust steam from the fan engine will suffice to dampen the air except in the coldest weather. After a mine has been thoroughly moistened, a slight shortage of water in the intake air for a week will not prove serious, and in most of the coal fields of this country cold waves do not last long. However, if a mine shows a tendency to get dry, some live steam will be needed to supplement the exhaust steam.

Many mining men have thought that the use exhaust steam would mean the presence in the int air course of a vapor so hot that the roof would sl and fall, as it does in some entries where a steam m is laid. Such is not found to be the case in pract The steam expands as it leaves the nozzles, and rap ly cools, so that 15 or 20 feet away the air curr feels merely warm even in medium weather, and feet away there is no perceptible warmth from presence of the vapor.

If the part of the entry close to the jets is p tected by lining or lagging, the roof will not be p ceptibly affected by the heat. Although moisture m have a bad effect on some roofs, generally it has b alternate wetting and drying that has caused roofs weaken.

The steam-jet method, if systematically used, make the ventilating current evenly humid. M mines that have introduced the method have exp enced no bad results. The cost of maintenance is tually nothing if steam is employed around the m and the exhaust steam is not otherwise used.

If the ventilating fan is driven by a slide-valve gine, as is usually the case, the exhaust steam th from is sufficient for moistening the air in all but coldest periods; then some steam from other sou may be needed. The efficiency of the method, w systematically followed up, has been shown bey question by its trial and adoption in a consider number of important mines.

Steam jets can not be used on a haulage road wl locomotive tenders, mule drivers, or trip riders employed, since the jets fog the air for a long tance and make the haulage difficult or danger Therefore, their application is generally limited mines that have pressure or blowing fans and do use the intake airways for haulage.

Steam Jets and Water Sprays Combined.

With the generally approved system of ventila employed in mines that make an appreciable quan of methane, haulage and travel are not allowed in tries carrying the return currents, but only in the take entries. Where this system is used and no h age is done except on the day shift, a combinatio water sprays and steam jets has given good res When trips are being hauled over the road the w sprays are used. In cold weather these sprays m be situated so far inside the mine that the incon air will not freeze them. During the night, or w there is no haulage to the outside, the exhaust st sprays are turned on at the mouth of the intake the main entries thoroughly dampened. In this a small number of water sprays help to keep the m moist during the day shift.

Use of Calcium Chloride.

Another method of keeping down coal dust is using a deliquescent salt, one which slowly disso by absorbing moisture from the air. Calcium chlo is such a salt. It has been used for a couple of y at coal mines near Welch, West Virginia; also at eral mines in different parts of this country.

...y crude calcium chloride, as sold by dealers, con... 60 per cent. or more of calcium chloride; the ... 40 per cent. or less is chiefly common salt (sodi... chloride). The latter, if pure, does not absorb mo...ture from the air and is of no value for laying dus... Pure calcium chloride can absorb three or four tim... its weight of water.

I... the larger cities of the eastern part of the United Sta...s calcium chloride costs, in carload lots, from $14 to $8 per ton. It may be bought in three forms: Dis...solved, solid, or granulated. The solid form, which co...s in large drums, contains a high percentage of wat... and has to be broken for use. This form is not as ...nvenient for mine purposes as the others. The gra...lated form is easy to scatter along an entry, and ...f it is packed in air-tight cases, so that it can not ...bsorb moisture during shipment and storage, it is the ...est form to buy.

T...ere are two ways of using calcium chloride. One way ...is to dissolve 5 or 6 pounds of it in 100 pounds of ...ater and sprinkle the solution along the road-way ... by water cars or by hand pumps. The salt must ...e used in this way in order to moisten the ribs, roof, and ...imbers.

T... other way to use calcium chloride is to sow the gra...lated form broadcast. This method is especially suite... for dampening gobs or the floors of entries; on road... where coal dust is thick it gives much more last-ing ...sults than does sprinkling. The little granules of th... salt lie on the surface, and by the moisture they abso... from the air they make the dust particles stick toge...er. After the surface of the dust in a road is thus ...moistened any new dust that falls upon it will stick ...nd get moist in turn.

A... person who intends to try the calcium chloride treat...ent for coal dust should remember that the crud... calcium chloride is not pure, and some that has been ...old contains so much common salt that it has little ...value for laying dust. In one instance brought to th... attention of the Bureau of Mines the substance sold ...s calcium chloride contained no calcium chloride at al... but was chiefly common salt.

Conclusions.

Th... mining engineers of the Bureau of Mines, from the ...periments they have made and from the facts they ...ave gathered in examining hundreds of coal mines ... believe that explosions of coal dust can be pre-vente... by proper care. Furthermore, they believe that ... though the use of any one of the methods de-scribe... in this circular may be difficult and expensive ...nder some conditions, there will be little danger of a wides...read dust explosion at a mine where any one of th... methods is properly carried out.

Th... engineers of this bureau believe that, although ...many mine operators have taken great pains to pro-tec... miners from most of the dangers of mining, the pr...a...tions regarding dry coal dust are not always co...p...te. Some operators who keep the main roads free ...om dry coal dust do not make sure that in all parts ...f the mines the dust is in a harmless condition. Hence it sometimes happens that a blow-out shot or a small ...xplosion of gas sets fire to the dust in a dry room ...r a dry heading, and the resulting explosion crosse... an area that was kept so damp that a dust ex-plosio... could not have originated within it.

It ...ust be remembered that after a dust explosion ...s d...veloped the shock and the flame are so strong that ...ightly dampened coal dust may be caught up ... ...ited to spread the explosion. It must also be ...mbered that a dry area usually contains more dust than can be completely burned by the oxygen that is at hand. So if an explosion gets a good start in such an area, it may have strength enough to carry burning and unburned dust into and perhaps across a dampened area. The latter, though it may furnish no coal dust, can supply the oxygen needed to burn the dust carried over from the dry area.

In a recent mine disaster in this country the explosion travelled 1,500 feet along a slope that had been washed down with hose just before the explosion and even had a wet floor after the explosion. The explosion burst forth from the slope mouth in a great flame and deposited much coked dust on the timbers of the trestle. The flame and the thick crusts of coked dust showed how great was the quantity of unburned dust and gases that had been carried for 1,500 feet along a slope that was so damp it might have been considered

Precautions.

In a mine working a coal that makes inflammable dust, the risk of a dust explosion can be greatly lessened by following these precautions:

Use permissible explosives where the coal can not be wedged down, and use them in the ways suggested by the Bureau of Mines in Miners' Circular 2.

Don't use black powder, dynamite, or any long-flame explosive.

Don't blast the coal "off the solid." Undercut it or shear it, and wedge it down if possible.

Don't drill the holes beyond the undercutting or shearing.

Don't fire two shots at once, except by electricity from outside the mine. Allow enough time between shots for the dust to settle.

When shots throughout a mine are fired after the shift by shot-firers, they should be fired on the last of the air first, then successively toward the intake, so that the dust and gases from the earlier shots will not be carried towards and possibly ignited by the later shots.

Don't tamp shots with coal dust, bug dust, or small coal, whether wet or dry. Use clay or other material that will not flame.

Lead out all coal dust or bug dust from the working places and do not let it collect along the roads. It is dangerous in the mine; it has value as fuel outside.

Use tight cars and keep the coal below the sides of the cars.

Flush the tops of the loads with sprays.

Remember that a dry mine is a dangerous mine.

Wash the coal dust from the roof, ribs, and timbers; or, if this is not done, keep the dust damp by making the mine "sweat" all winter as it does in summer; or else keep the coal dust covered with rock dust, clay, or similar material.

Don't be satisfied with having some parts of the mine wet.

Keep all the mine wet, so wet that the roof and sides are beaded with moisture and the dust packs down on the floor and looks wet.

Although in the year only 150 tons of tungsten ore were marketed, the present annual consumption is well over 4,000 tons of concentrated ore carrying from 60 per cent. to 70 per cent. tungstic oxide.

The Tilt Cove Copper Company, Limited, operating at Tilt Cove, Newfoundland, earned a gross profit during the calendar year 1911, of £12,152 8s. 2d. The company is a subsidiary of the Cape Copper Company, Ltd., a London concern that was organized in 1863. The Tilt Cove mine is held under a 99-year lease, expiring 1989.

On the Organic Origin of the Sedimentary Ores of Iron and of their Metamorphosed Forms: The Phosphoric Magnetites.

Read before the Iron and Steel Institute by W. H. Herdsman, Glasgow.

There is, I am aware, nothing new in attributing the formation of the phosphoric ores of iron to organic agency. The subject, however, has not yet, in my opinion, received the attention which it merits.

I bring it before you, therefore, for consideration and discussion, as these ores are of increasing importance to the steel industry on account of the growing scarcity of non-phosphoric ores, while the sedimentary ores appear to exist in practically inexhaustible quantities, and must form the basis of our calculated supplies in the not very distant future.

The oolitic or pisolitic structure of so many of the sedimentary ores of iron, and the phosphoric character of all, have long led me to see in those features evidences of an organic origin, a view our advancing knowledge of the numerous micro-organisms at work in nature tends to support, bringing, as it does, to our notice many forms apparently adapted to play the part of builders-up of iron ore deposits.

Perhaps the strongest evidence bearing on the subject is afforded by the deposits of bog iron ore which are to be seen in many countries in process of formation, and have been shown to be due to the activity of organisms, generally identified as bacteria, in the ferruginous waters.

There is no doubt that several genera of bacteria have been definitely recognized as habitually precipitating iron from its solutions; they bear names in inverse ratio to their own length (with a list of which I need not trouble you), and are generally known as "the Iron Bacteria." The Russian bacteriologist, Winogradsky, has claimed that the deposition of iron by these bacteria is not a mechanical process, but is due to the physiological activity of the organisms, which liberates energy by oxidizing ferrous oxide in its protoplasm, ferric hydrate being formed, which accumulates in the sheath and gradually passes into the more insoluble ferric oxide. Dr. Hans Molisch, of Vienna, however, contests this physiological action, and Dr. David Ellis, of the Technical College, Glasgow, the leading British authority on the iron bacteria, is, pending further investigation, in agreement with Dr. Molisch.

Putting aside, however, the character of the action by which the precipitation is effected, it has been proved that many of the bog ores are almost entirely composed of the ferruginous walls of the thread bacteria B. Gallionella and Leptothrix.

Dr. Molisch, in a recent work, shows photomicrographs of a Siberian bog ore consisting of the "rust-red" walls of Gallionella Ferruginea and Leptothrix Ochracea; he also shows a similar ore from Plass in Bohemia, which consists largely of the remains of the Chlamydothrix Ochracea. Dr. Molisch was one of the first to point out that Leptothrix have also the power to store up manganese oxides in their walls, and so form ore masses of this metal. He also noted that the same bacteria can alternately precipitate iron or manganese according to the character of the solutions available.

D. D. Jackson, an American authority, has further described a new species of Crenothrix which he named C. Manganifera, the remains of which in one case he found to consist of 34 per cent. of manganese o and 14 per cent. of iron oxide, while in other c the manganese oxide varied from 30 to 66 per c with varying smaller amounts of iron oxide.

We have Dr. Molisch's authority for the state that apart from the iron bacteria there are othe ganisms which have the power to convert soluble of iron and manganese into insoluble forms as ox He especially mentions certain confervoid alga which class the diatoms also belong, and a marin ganism, Cocconeis, which surrounds itself wit brown covering of manganese oxide.

A quite accidental confirmation of the state that other organisms have the power to deal with oxides was afforded me recently, when a sampl iron ore, which, with a number of other mineral ples, was lying on a wooden shelf in a somewhat situation in my coach-house, was attacked by a gus, which Dr. Ellis has been good enough to inde for me as that of ordinary "dry rot." The whole of fungus growing between the shelf and the gradually assumed a reddish hue and threw off s of oxide of iron which covered the shelf below w red powder, giving, on assay, the same iron con as the ore attacked.

It is notable that of about ten pieces of diff minerals in the same parcel only the iron ore w tacked, and on the iron ore being removed, the f gradually resumed its normal colour, and the sl of mineral dust falling from it ceased.

This illustration of the fact that apparently forms of organisms will act as precipitants of oxides may help us to understand the varied under which the sedimentary iron ores are found differences of the several beds of the Clevéland colnshire, and other ores may evidently be d varying climatic and other conditions favouring one and then another type of organism agent deposition, during the period of their formation. greater differences which are found between the mentary iron ores of the different geological p may be similarly explained.

During the earlier geological times bacteria probably diatomaceæ, may be assumed to have the principal agents at work, giving us the pe and generally siliceous ores of the Cambro-Si age; while, with the gradual development of o life, we have the protozoa and calcareous ele brought into play, the former acting through th ganisms, or, as calcareous nuclei, acting chem together with numerous molluscs similarly a would contribute to the ores of the later periods more highly calcareous and variable phosphoru tents.

To some it may appear difficult to understan organisms so minute as bacteria, of which son millions are required to cover a square inch of s should be capable of forming ore deposits which amount to thousands of millions of tons, yet w learn of the rapidity with which they multiply sion under conditions favourable to their grow development, we see that, given those favourab ditions, the dimensions of the deposits can o

ted by the supply of material—that is, ferruginand phosphoric solutions available.

s regards the phosphoric contents of the sedimentr ores of iron and its relationship to their organie orin, the association of phosphorus with living matters of ancient date, and it is well known that phosphrus in a soluble form must be supplied to all land, grving crops. Tests recently carried out by me show the presenee of 5.28 per cent. of phosphorus in the ash of he "dry rot" fungus already mentioned, while in the ash of ordinary mushrooms I found as much as 6.8 per cent. In a sample of seaweed I found 1.86 per eent. phosphorus in the ash, equal to 0.104 per cer in the plant itself. The highly phosphoric contens of bog iron ores which are shown to be compos of bacteria remains, confirms the phosphorie haeter of those organisms also.

Te very considerable variations of the phosphorus corents in the different sedimentary ores may be asund to be due to the different organisms concerned in heir deposition, and possibly also to the varying degee in which the matter of the organisms itself ma have become incorporated in the ore deposits.

Tough the phosphorus present in iron ores is inarbly of organic origin, it does not always indicate an rganie origin of the ore itself. Some fifteen or twety years ago some shipments of Elba iron ore sent to is country were found on analysis to be higher in hosphorus than usual, parts showing as much as 1 5 er cent. phosphorus. As the Elba ore had hither to en one of the purest of our ore supplies, this aud some consternation to the parties interested. and I was sent out to the island to investigate the matr. I was able to trace the phosphoric ore to the sumit of a hill not far from the coast, and came to the onclusion that the excessive phosphorus contents of hat part were due to it having at some remote perid been the haunt of sea fowl, the guano deposit of hich had in the course of time become incorporated with the surfaee layers of the iron ore masses at that point.

M explanation, I remember, was ridiculed at the time by one of our leading luminaries, but has since been amply confirmed by similar experiences in insula positions elsewhere.

On the connection of the oolitie structure with the rganic origin I do not dwell, as at present I have no evidhee to offer.

I propose now to deal with the phosphorie magnetites especially those of Swedish Lapland, my remarks being suggested by a recent purusal of the Carnegie Researeh Report, by Dr. O. Stutzer, on the "Geology and Origin of the Lapland Iron Ores," published in No. II. of the Journal of the Institute for 1907. Dr. Stutzer appears to have made a very careful examination of these ore fields, and reviews impartially the various theories regarding their origin, and the evidence by which they are supported, his own conclusions, however, invariably being that they are magmatic segregations in depth, which, with their enclosing crystalline rocks, have been injected to their present position.

I find myself entirely at variance with Dr. Stutzer on his conclusions, which, in my opinion, are also contrary to the mass of evidence he adduces to support them and as the problem of the Lapland ores has, since my own brief visit, appeared to me a simple one, I propose to submit my views for eritieism and comparison with those of Dr. Stutzer and others, set out in the paper referred to.

My opinion is that the Kiruna and other phosphoric magnetites of Sweden are sedimentary ores of organie origin of Cambro-Silurian age, similar to and probably eontemporary in deposition with the Wabana ore beds of Newfoundland. These Swedish deposits, together with their containing rocks, have been metamorphosed by heat of dynamie origin, due to compression caused by the shrinkage of the earth's crust, to which foree all volcanie aetivity is probably due. The evidenee of this action is the tilted position of the ore bodies; the ore was brought to a state of fusion, or an equivalent physieal condition at the great depth at which this action took plaee, and the peroxide particles have been converted into magnetite, which appears to be the ultimate produet of thermal metamorphism. The particles of this magnetite have segregated into the dense form in whieh it now exists —the silica, alumina, and lime of the sedimentary ore passing into the composition of the containing clays, shales, etc., whieh now, by semi or complete fusion, are transformed into the gneisses, porphyries, and syenites associated with the present ore masses.

In the Kiruna distriet the ore and rocks have been subjected to a higher temperature than at Gellivara, where the granular strueture of much of the ore probably represents the remains of its original oolitie strueture, and the gneisses the ineomplete fusion of the shales whieh contained the original ore beds.

That the width of the ore body at Kiruna is greatly in excess of any known sedimentary iron ore bed is explained by presuming the segregation of several ore beds into one body, their partings naturally uniting by fusion with the adjacent roeks, while some further thickening would probably occur by the action of gravity on the tilted ore mass; it is notable that the greatest thickening occurs at Kiruna, where there is also evidence that the highest temperature and consequent greatest approach to fluidity prevailed.

From Dr. Stutzer's paper I find that a sedimentary origin for the Lapland deposits is advocated by Sjogren, Hamberg, and De Launay, though none of these authorities appears to offer any definite explanation of the subsequent metamorphosis.

That the ore beds form part of a regular sedimentary series is shown by the section given on p. 117 of Dr. Stutzer's report, and is confirmed by all the evidence he has collected.

When the series became heated by the pressure which brought about the metamorphosis of the ore into magnetite, the highly alkaline fueoid elays enclosing the ore beds would naturally be the first to soften and fuse, while the more acid members would be metamorphosed without fusion, or the loss of their sedimentary identity to the sehists and qnartzites as they now exist. The specular ore deposits of the quartzites frequently referred to by Dr. Stutzer are of quite different origin, being non-phosphoric impregnations of the original sandstones, which have been segregated and metamorphosed during the period of high temperature into their present specular condition. They are of the same elass and type as those found throughout the northern parts of the Seandinavian Peninsula constituting the ores of Dunderland and Sydvaranger. The ore is frequently mixed specular hæmatite and magnetite, showing an ineomplete stage of metamorphism due to thermo-physieal eauses respecting whieh we are at present imperfeetly informed. The complete transformation of peroxide ores into magnetite is apparently only brought about when actnal fusion results.

To Dr. Stutzer and other advocates of a magmatic origin for these and similar deposits I would point out that the magnetite which is contained in the accompanying crystalline rocks is invariably titaniferous, as Dr. Stutzer himself records in so many of his observations, and as the iron sands resulting from the disintegration of such rocks are always found to be. The analysis of the Kiruna syenite given in Dr. Stutzer's paper on p. 113 shows that the magnetite yielded by segregation from such rock would contain 20 per cent. of titanic acid, while the Kiruna ore contains but traces of this substance. As Dr. Stutzer admits or claims a contemporary origin for the syenites and the ore bodies they enclose, I shall be interested to learn how he reconciles these facts with a magmatic origin for the ore. Had Dr. Stutzer checked his observations more frequently by chemical analysis, he would, I think, have avoided many pitfalls and arrived at a different conclusion.

In supporting the theory of a sedimentary origin for these Lapland ores, I would draw attention to the fact that similar iron ore deposition is now going on in the same district, and probably under very similar conditions to those prevailing when these great deposits were laid down.

Dr. Stutzer notices the occurrence on pp. 108 and 111 of his paper without apparently appreciating the relevance of the matter to the subject he was studying. He says: "In the numerous peat-bogs the iron of the more ferriferous rocks has been largely changed by reduction to an organic ferrous salt, which, when removed in solution in running water, is re-oxidized to ferric hydrate, furnishing material for lake and bog ore deposits." And again he says: "The innumerable peat-bogs of Lapland have a powerful solvent effect on the more ferriferous rocks, the dark red porphyries being soon bleached white; the iron-laden bog waters collecting and stagnating (?) in ponds deposit their contents as a dark brown ferric hydrate."

Here Dr. Stutzer has accurately noticed and recorded natural processes of iron ore deposition going on, which we have every reason to believe have gone on through all the cycles of the geological ages. These processes, which modern science enables us to trace to organic agency, furnish, I submit, a simple and natural explanation of the origin of these deposits more probable and more convincing than those requiring us to accept them as deep-seated magmatic segregations, subsequently injected to their present positions, or as of "pneumatolytic hydatogene" origin, "derived from gases in solution in the magma or contact deposits." That they are of sedimentary origin, however, is, I think, rapidly becoming the accepted belief, and in claiming, as I do, that their metamorphosis has been caused by heat generated in the constant shrinkage of the earth's crust, always steadily going on, with the consequent folding and compression which is every where apparent where igneous and eruptive manifestations are found, I am again looking to a simple and natural agency to explain their present condition.

In support of my views I would point out that—

(1) The general alignment of the magnetite outcrops, and the continuity of the deposits in length and in depth where worked or tested, correspond in every way with the extensive areas generally covered by sedimentary iron ore deposits.

(2) The average phosphorus contents of these deposits (the magnetites) is everywhere from 1 to 2 per cent., agreeing in this important respect with sedimentary deposits of similar geological age.

(3) In the Annapolis-Torbrook district of Nova Scotia the metamorphosis of a sedimentary hæmatite into a phosphoric magnetite can be definitely traced

(4) Mr. L. Cayeux has shown that the magnetite ore of Dielette, France, is a metamorphosed sedimentary ore, as it still preserves a typical oolitic structure

In conclusion, I may note that a consideration of the organic origin of certain ores of iron has incidentally brought to notice the fact that manganese ores may be similarly formed.

It throws more light on the close and constant association of the ores of the two metals in nature, and suggests that organic agency may have been responsible, at least in part, for the great sedimentary manganese beds of the Caucasus and South Russia which frequently show an oolitic structure, and other manganese deposits elsewhere whose sedimentary origin has been lost or obscured by subsequent metamorphism. With respect to the connection which I have endeavoured to show between the phosphoric magnetites and the sedimentary ores of iron, it is evident that the acceptance of my views would recognize, in the metamorphic action, a natural refining process which has thrown out the earthy constituents of the sedimentary ores and raised the metallic contents of the metamorphosed product to a high degree of concentration.

If this be so, then the same refining and enriching process may be expected to be met with elsewhere wherever sedimentary ore beds have been subjected to disturbance by earth movements from their original horizontal position, the degree of enrichment being proportionate to the dynamic force developed and the thermal equivalent resulting therefrom.

In preparing this paper, I have to thank Dr. L. Ellis, of the Technical College, Glasgow, for much valuable information respecting the iron bacteria, of which, as is well known, he has made a special study.

Methods of Removing Slag at Granby Company's Smeltery, B.

The Granby Consolidated Mining, Smelting, and Power Company, Limited, is preparing to dispose of the slag from the blast furnaces at its copper smeltery at Grand Forks, Boundary district of British Columbia, by a different system to that in use there, which latter has been for years the hauling from the furnaces to the dump, of the slag while hot in cars by steam locomotives.

The extent of the smelting operations of this company, the smeltery of which is stated to be the largest copper reduction works in the British Empire, and among the biggest in the world (second only to the great Washee works at Anaconda, Montana) is indicated in the following brief outline of the smelting plant and equipment in use at Grand Forks. At the smeltery there are eight rectangular, water-jacket blast furnaces—six 44 by 266 inch, and two 48 by 240 inch, at tuyeres, depth 15 feet 8 inches—having a total capacity of 4,000 to 4,500 tons of ore per diem. Connersville blowers, with a total air capacity of 60,000 cubic feet; specially designed mechanical furnace charging system; hot slag haulage, by 14-ton steam locomotives in 44-cubic ft. slag cars; three converter stands, 84 by 126 inches, operated by electricity

and, 72 by 100 inches for which hydraulic power d, converter capacity being 50,000,000 pounds of r per annum; three blowing engines, total ca- 19,700 cubic feet of air per minute, and much ory plant and machinery.

ing the earlier years of the company's smelting ions the slag was granulated by water and run dump by gravity, in the ordinary way. Then, as mp filled to an extent making it difficult to main- he grade requisite for the continuance of this d of disposal of the slag, it became necessary stitute for it the hot slag haulage system now to be dispensed with in favour of a return to lation by water and disposition of slag by a me- escribed as follows:

r large receiving bins will be erected below the t level of the slag dump and at a distance of 150 feet from the blast furnace settlers. The ill be granulated by water immediately after its rge from the settlers, in the ordinary way, and veyed thence to the receiving bins in launders. the bins it will be distributed over the dump by s of conveyor belts, at first up a gradual incline aximum height of about 100 feet, and then by a onveyor to the place for dumping. These belts e ordinary 30-inch conveyors. The incline will t be over a series of trestles, but afterwards the of the dumped slag will be so regulated as to give quisite incline up to whatever height it shall be economically practicable to carry it. The con- belts will be operated by two electric motors. Arrangements are being made for the supply of lumber for construction of the receiving bins, trestles, launders, etc., and the excavation of trenches for the launders from the settlers to the receiving bins is already in progress.

Two main reasons have caused the management of the company to make this change in the method of disposal of slag. One is, the excessive cost of the present hot slag haulage system, owing to the slag having to be hauled about three-quarters of a mile to the dump, together with the high cost of maintenance in good working condition of locomotives and slag cars; and a second, the increasing difficulty of disposal as the dumping room below the present level becomes more and more curtailed. The substitution of the new method of slag disposition for that long in use is expected to involve an outlay of between $30,000 and $40,000, but important compensating results will be lower cost of disposal of the slag, and provision of dumping room for fully 10,000,000 tons of slag. To long continue the present hot-dumping system would mean the changing of the course of the north fork of Kettle River, with resultant cost of land that would be destroyed thereby, so the change determined upon will avoid a large expenditure in that direction and at the same time bring about a substantial reduction in operating costs. It will probably be about four months—near the end of September—before it will be practicable to make the change now being prepared for; meanwhile the slag will be dumped while molten, as during several years last past.

THE ST. ANTHONY GOLD MINE.

OR'S NOTE.—The following article was written at th request of the Journal. It is based upon a pri- vate eport compiled by Mr. J. C. Houston. The ob- ject appending the lengthy assay sheet is to adduce evide ce of the possibilities of the region. The present owne s of the St. Anthony are floating no company. Whil we cannot, of course, assume responsibility for the accuracy of the samples and assays, we are satis- ied at they have been done honestly and carefully.

General View of the Buildings

Office, Storehouse and General View of Harbour

(Written for the CANADIAN MINING JOURNAL.)

The building of the new transcontinental railroad through Northern Ontario and particularly through that ction of Ontario north and west of Port Arthur now as Sturgeon Lake district, has made readily ac- ssible and brought into some prominence the gold bearing areas in that locality. On account of the inac- ssibility of this district little development work has been done in the past on the numerous prospects staked along the shores of Sturgeon Lake, although specimens of visible gold-bearing quartz of almost incredible richness have been brought into Fort William and Port Arthur, which were reached in the old days by one hundred miles of lake and river navigation and then by the Canadian Pacific Railway from Ignace.

To those who are not familiar with the location of this gold field, it may be well to explain that the route from the east is, first to Fort William via the C.P.R., this city being eleven hundred miles west from Montreal, eight hundred miles west of Toronto, and about four hundred miles east of Winnipeg. From Fort William a branch of the Grand Trunk Pacific is now open for traffic as far west as Superior Junction, one hundred and eighty miles distant. The new line of the Transcontinental Railroad is now being built east from that point, and it is inside the angle formed by the junction of the two roads that the Sturgeon Lake gold district lies. The lake itself, lying northeast and

Open Cut running north from the shore of Coture Lake.

southwest, practically forms the third side of a triangle, for its northeast end reaches within three and one-half miles of the main line of the G.T.P., while the south end, or the foot of the lake, is within six miles of the Port Arthur branch of the G.T.P.

As much of the supplies for the building of this section of the Transcontinental Railroad east of Superior Junction were brought in over the lake, the contractors found it advantageous to connect the foot of the lake with the railroad by a six-mile spur. They then established a boat service on the lake, so that there is now a continuous water and rail connection with the outside world. In the old days freight was taken in by canoe from Ignace with great hardship, often at a cost of $200 a ton; but now it may be billed through from any point and at most reasonable rates. The contractors announce that they are going to operate their spur line and boats to the advantage of mining people in the district. Once the main line of the Transcontinental is in operation facilities for getting in freight will be even better and the rates lower. Since nearly all the properties now being developed in the Sturgeon Lake district are either on islands in the lake itself, or on the shore, and since steamers are now landing passengers and freight on the docks of all of these, it will eliminate much of the hardship and expense of other days, and rapid development of the more able properties is sure to follow.

Sturgeon Lake itself is a beautiful body of about 36 miles long and of varying width, som up to two miles. There are numerous islands great many bays in the lake, the shore line of is clothed with spruce, balsam, jack pine, popla The country generally is rolling and is the ha many of our large game species. The lakes ar stocked with fish, the large grey trout predomin

A visit to the various claims now being dev in this district shows that the summer is to be one. At the Rainbow property, which is situat an island about midway in the lake, there is a sh of blue quartz in a vein some 30 inches wide carries values on the surface, and in the shallo which were sunk on the vein. The values also into the wall rock for about two feet, thus gi probable total width of about four feet of milli This property is owned by English capitalist work is being pushed vigorously under the supe of a mining engineer of wide experience in Au and the West African gold fields.

Besides the Rainbow property there are many locations upon which a good deal of work ha done, such as the Douglas, the Dawson, the W the Faucett, and the Covenay. None of these ever, has reached the producing stage. The onl perty on the lake that has been developed th is the St. Anthony, which is situated at the h the lake and which has recently been acquir Toronto investors. The property is in charge J. C. Houston, formerly manager of the Right o mine, Cobalt. Mr. Houston, "Joe" to his fan is thoroughly acquainted with the Rainy Riv Lake of the Woods mining camps.

The following facts are taken from Mr. Ho report. The samples were taken by him and a under his supervision:

Geological.

The main vein has a north and south course. the contact between the schist and granite ru northeast and southwest direction with a varyi towards the southeast. Thus the values are pa schist and partly in granite. The character enclosing rock does not seem to have much influe the ore as the samples show just as favourably north end which is altogether in the granite, as south end which is wholly in the schist. The v the schist appear to have more regularity than granite. All of the ore so far mined on the pr has been taken out of an open cut at the south indicated on the plan and longitudinal sketch herewith.

Old Tailings Dump

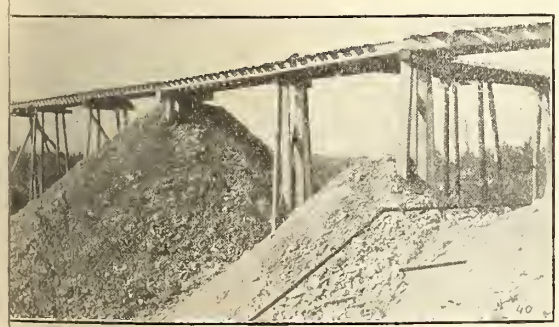
Longitudinal Section.

s open-cut begins about four feet above the water of Coture Lake, and continues for about 145 It then dips down about 40 feet to the tunnel formed the 100-foot level. It extends along this for about 100 feet and then angles up to the surt about 60 degrees. This section has been stoped om 10 to 25 feet wide and while some waste was led the greater portion of it was ore.

A rift was run south on the 100-foot level from the bottom of this open-cut for a distance of about 45 feet and a winze sunk there, to a depth of over 50 feet. Good ore was opened up in this drift, the whole length of it showing $25 to $40 per ton. In the winze the vein dips to the west and consequently passed out of the shaft which was sunk vertically at a depth of 40 feet. This also showed good ore, as it gave an average from about 20 samples of $19.20. The open-cut immediately over the winze gave assays of $39 and $42 over widths of 14 and 12 feet respectively. At the north end of the open-cut the vein split into two portions, the easterly portion of which was drifted on at the 100-foot level, as indicated by Stations 15, 14, 13, 12. Good ore shows all the way along at that level. At Station 12 it shows four feet of $20 ore. At this station a cross-cut was run to the west for a distance of about 70 feet; it then curves to the north past Station 8, where it encounters the west section of the large vein. Here no values of any particular moment were shown up for nearly 100 feet; but close to Station 3 values begin to come in and for a distance of 120 feet along the drift and up the raise to the surface there is pay ore. On an average of about 45 assays this ore runs $23.60 to the ton. On the surface this section of the vein shows from 12 to 25 feet wide, and where the raise holes through to the surface there is over 30 feet of ore that will run from $7 to $8 to the ton.

Continuing north from the bottom of the raise, considerable dead work has been done. There is a drift north from Station 8 about 150 feet in length which is in absolutely barren ground. At Station 10 this drift turned sharply to the west, and as soon as the vein was picked up, the work in that direction ceased. At Station 2 a cross-cut has been run over to the east to connect with the main shaft and continued eastward for about 130 feet. About 50 feet to the east from the main shaft this cross-cut intersects the vein that was known on from Station 12, and at the intersection the assay return was $35 over a face of four feet.

Number two vein, which shows on the surface, for about 200 feet in length and has a varying width of from 8 to 12 feet, gives assays of from $2.40 to over $4. On the surface No. 1 vein can be traced northward from where the raise holes through to the surface for a distance of about 300 feet, and shows a varying width of



Ore Dump

Surroundings where the 100 ft. level holes through to the surface.

from 6 to 12 feet. On the north end of this surface showing two pits have been sunk, and three assays taken from these pits give the following results: $7.60, $24.80, and $8 respectively. No. 1 vein does not end where these pits are sunk, but apparently outcrops across a swamp 1,000 feet further on. It was surprising to find that here in this section about which little is known, there was to be found a property with over 1,000 feet of drifting at the 100-foot level, with a main working shaft sunk for a distance of about 120 feet, and at a distance of about 400 feet from the main shaft was a winze sunk to an additional depth of 52 feet, with good ore showing in it down past the 40-foot mark.

Assay Sheet.

The old mill equipment used by the former o is being partly discarded and largely supplen by the present owners, who expect that by July they will have installed and in operation a co 10-stamp mill, with a six-foot pebble mill for re- ing purposes. There is equipment of two 80- power boilers, a 40-horse-power Corless engine, cross-compound compressor, 4-drill capacity, a hoist with three hundred feet of cable, a co outfit of water pumps, water tanks, etc. The m shop is provided with a large lathe, a drill press er, and other necessary equipment. The assay is also in good shape. As will be seen by the graphs furnished herewith the property is wel pliced with buildings, there being a sleeping ca cook-house, and other buildings large enough commodate a force of 40 or 50 men.

At the present time the fuel supply for the pr is being obtained from the forest of the surrou country, but there is every reason to expect that in a comparatively short time it will not be nec to depend on the timber growth for fuel, as th a large water fall on the Sturgeon River about miles from the St. Anthony which will furnish sufficient to supply all the needs of the Sturgeon Gold Fields even if developed on a very large

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Dominion Coal Output.

The output obtained from the mines of the Dominion Coal Company in May was as under:—

No. 1	50,770
No. 2	69,070
No. 3	18,710
No. 4	39,670
No. 5	32,140
No. 6	23,240
No. 7	14,580
No. 8	14,580
No. 9	34,490
No. 10	16,770

No. 12	22,010
No. 14	11,300
No. 15	2,300
No. 16	1,150
Tons	350,770

This is the largest production ever obtained by the Coal Company in May. The nearest record was in May, 1908, in which month the output was 335,829 tons.

The production for the five months ending May, during the present and recent years, is as follows:—

1908	1,585,364
1909	1,273,676
1910	1,196,917
1911	1,523,190

While the output is some 326,000 tons ahead of last year at the end of May, yet it is 62,000 tons behind the corresponding period of 1908. The first seven months of 1908 produced 2,-000,000 tons, and it is not likely that this output can be reached by the end of July this year. The last half of 1908, however, was a very poor one, as shipping was hindered by forest fires and fogs in the St. Lawrence, and a marked trade depression was making itself felt. It is hoped during the coming summer to maintain the present rate of output, and it is reasonably probable that the output for 1911 will reach over 800,000 tons, and get away from the 3½ million mark around which Dominion Coal outputs have so persistently hovered for six years.

Dominion Steel Corporation Employees' Debentures.

As intimated by the president of the Dominion Steel Corporation at the annual meeting in Montreal, this corporation has taken the commendable step of issuing 6 per cent. debentures to their employees in such low denominations as $50 and $100, and on an easy instalment-purchase plan. These debentures are issued only to employees or the trustee or benefit societies connected with the corporation or its subsidiary companies. The scheme, therefore, embraces employees at the Sydney Steel Works, the Marble Mountain, and other limestone quarries of the Steel Company, the ore mines at Wabana, the mines and works of the Dominion Coal Company, and at the Springhill mines. The debentures may be paid for in sum, or in 24 or 36 monthly instalments, which will be deducted from wages. Once the instalments are all paid the debenture is transferable, being made out to bearer, but it is not transferable in course of purchase, except to another employee of the corporation. If a purchaser desires to surrender his rights and discontinue the instalments he may do so, and will be allowed ordinary bank interest on the accumulated instalments. Provision is made for temporary suspension of payments when circumstances render this necessary or desirable. A most attractive feature of the issue is that if a purchaser should die before his instalments are paid up, the corporation will itself pay up all instalments due after his death, treat the debenture as fully paid up, and his representatives may at once receive the debenture, or its face value in cash. The debentures run for six years, and the holder, if he is still an employee at the end of this term, may receive the face value or a renewal debenture on which interest will be paid at not less than 5 per cent. per annum.

It is probable that this debenture issue will be largely taken up, as it affords a real necessity among an industrial population earning fair wages, namely, an absolutely safe investment returning twice the interest rate allowed by savings banks. The usual bond issue in denominations of $500 and $1,000 is altogether out of the reach of the thrifty workingman, but there must be a great number of men with a few hundred dollars who will welcome this issue, particularly with the added insurance provision. There are also large numbers of young men, earning good wages, who can easily find the small instalments of from $1.30 to $4 monthly required to purchase a $50 or a $100 debenture, who will find this form of investment an excellent way to accumulate the nest egg necessary for marriage, or old age.

The following interesting paragraph appeared in the "Colliery Guardian" of the 12th May:—

"At the Mansfield colliery, belonging to the Bolsover Colliery Company, as the result of one week's working of 5½ days, ending Tuesday, May 2nd, a record for a week's turning was made, the total quantity of coal brought to the surface being 25,068 tons. This gives an average turning of over 4,557 tons each day, or 620 tons per hour. It is worthy of mention that during the year 1910 not a single fatal accident occurred at the pit."

This is a record to be proud of so far as production goes, but to mine over a million tons of coal without a single fatal accident is a far greater reason for congratulation. The Bolsover Colliery Company's mines are in the northern portion of the Derbyshire and Nottinghamshire coalfields in the English Midlands, and this company has always been known for its solicitude for the safety and comfort of the workmen. The colliery village of Bolsover is a model of what a colliery village should be. It was laid out with this intention and has justified the expenditure and thought that was devoted to this end.

The Springhill Strike.

The Springhill strike was called off on the 28th May by a unanimous vote of the men, having lasted from early in Augnst, 1909. The date recalls the fact that just one year and one month from this date the Glace Bay strike was declared off, the vote to return to work having been taken in this case on the 28th April, 1910. Springhill is a place that has an unenviable notoriety for strikes, but it is to be hoped that the strike which has just closed will have satisfied even the most inveterate advocate of strikes for a long time to come.

The strike followed upon the refusal of the men to accept the findings of a Conciliation Board. The demands of the men were for recognition of the U.M.W.A., for an increase in wages, and the adoption of a fixed wage schedule, and payment for the coal produced by the ton and not by the box, with a modification of the system of docking for stone. The Board refused to recommend any of the demands of the men, but suggested an arrangement in connection with docking for stone, which the men rejected.

Shortly after the commencement of the strike the Cumberland Coal & Railway Company announced that the strikers would not be taken back to work except under a reduction of 15 per cent. in the wages of coal cutters.

Towards the end of 1910 the Dominion Steel Corporation purchased the stock of the Cumberland Coal & Railway Company, and attached the Springhill mines to the properties operated by the Dominion Coal Company.

The militia were called out in July, 1910, to repress disorder. Owing, however, to the restrictions placed upon the military when acting in aid of the civil power, and the indifferent attitude of the town police of Springhill, the strikers for a long time had practical control of the town, and by a system of pickets were able to prevent any men returning to work. In March, 1911, the militia were withdrawn and the town was placed under the jurisdiction of a Provincial Commissioner of Police, who, with the assistance of 30 provincial constables, was able for the first time to put an effectual stop to the picketing and molesting of the men at work. Almost immediately following the arrival of the Police Commissioner, several of the most prominent strikers returned to work, and it was evident that many others were tired of the useless struggle and had only been deterred from seeking work by fear of bodily injury at the hands of the strikers.

At the beginning of the year the Provincial Workmen's Association revived the old Pioneer Lodge at Springhill. Nego-

tiations were entered into between the officers of the P.W.A. and the management of the Dominion Coal Company for a lessening of the 15 per cent. reduction announced after the strike was called, and endorsed by the Coal Company when it assumed the management at Springhill, for a modification of the docking arrangement and for consideration for abnormal working places.

The strike leaders began to realize that the situation was daily getting more hopeless for them, and the Police Commissioner approached the Premier with a committee of strikers seeking through his intervention to obtain terms from the Coal Company which would enable them to return to work. After negotiations extending over several weeks, the Coal Company agreed to take back the men who had been on strike as fast as places could be found for them, the company stating it believed it possible to do this within 45 days. The finding of the Longley Board is to govern the method of docking for stone. The wages of coal producers will be reduced 10 per cent. below those existing prior to the strike, but fair consideration will be allowed in abnormal places. No other reductions are to be made in day wages, the schedule which was announced by the Coal Company in January remaining in force, with the exception of the concession to the coal-cutters.

The net result of the strike is that the U.M.W.A. has not gained recognition, that the award of the Longley Board with reference to the docking system which the men refused is to become effective, and that instead of increased wages, the coal cutters will suffer a 10 per cent. reduction.

The United Mine Workers of America have spent a lot of money in Nova Scotia to little purpose. It is estimated that in the strikes at Springhill, Glace Bay, Morien, and Inverness at least $1,800,000 has been expended, and in each case the strikes were either abortive from the first or eventually unsuccessful. The chief reason for the failure of the U. M. W. to obtain recognition in Nova Scotia is that this organization is unnecessary. Taking advantage of an insignificant "insurgent" movement in the P. W. A., the U. M. W. attempted to usurp the jurisdiction of the Nova Scotian union, and posed as the heralds of unionism to a benighted mining population, ignoring the fact that Nova Scotia mines had been unionized long before the U. M. W. came into existence, and that the conditions under which Nova Scotian miners live and work are immeasurably superior to the conditions in the proper habitat of the U. M. W. of America.

Others reasons for the failure of the U. M. W. were the introduction of American strike methods, altogether foreign to Nova Scotian ideals, brutal and organized intimidation, the lavish use of union funds to corrupt those who could aid the strike cause or give the leaders information; the open advocacy of the extremest tenets of international socialism, and above all, the utter rottenness and insincerity of the whole U. M. W. campaign with its specious appeal to the foreign portion of the mining population and the newly arrived and credulous miner from the British Isles. The chief officials of the U. M. W. must have found it very difficult to explain, and more difficult to defend, the huge expenditure of union funds in Nova Scotia, where the status of the miner is higher than in any United States coalfield, where the fatality rate is lower and the conditions of living are better; where the true aims of unionism are better understood and practised than in any labour union affiliated with that reactionary and tyrannous body known as the A. F. of L.

Many of the miners of Nova Scotia were carried away by the midsummer madness of the U. M. W. agitation, and the unlimited promises of this union's paid organizers, accepting all too credulously the vapourings of migratory orators whose sole mission was that of destructive agitation. To-day the disgust of these men is all the deeper because of their first unsophisticated enthusiasm. Looking back over the past two years is to review the most disastrous period in the hist of Nova Scotian coal-mining, all the more to be deplored b of the entire needlessness of all the strikes which were at the mandate of the United Mine Workers of America. was not a grievance, real or fancied, in all the complai the U. M. W. which could not have been settled on terms without the intervention of this alien organizatio without all the loss of money, reputation, and trade whi been entailed upon the miners and the coal owners.

ONTARIO.

Cobalt and Gowganda.

The power situation is now all that could be desired an production from the camp is back at its former level in but owing to increased concentration is lower in tonnage the silver prospects with money in the treasury to resun velopment have commenced to search for the white again and there are probably as many men now employ Cobalt as during the past year and before the power sho But the speculative element has entirely disappeared, an less a property can actually show silver in a fairly conti ore body it is hard to raise money for development.

In the annual report soon to be published, the Buffalo will show a production of a million and a half ounces proximately the same as last year. 1,250,000 ounces wer duced at the mill from 41,000 tons of ore, or an avera about 30 ounces per ton milled. The ore reserves will proximately the same, about 41 million ounces, the old re of last year scarcely being touched. Much of the or year has come from development on the new level at th foot, and some old stopes on No. 10 vein.

The problem of the treatment of the low grade ore Crown Reserve and the Kerr Lake has been solved. I at first proposed to erect a customs concentrator at Kerr but there was a hitch at the eleventh hour and the schen through. Now an arrangement has been made whereb Nova Scotia mill treats both the Crown Reserve and the Lake ore at a certain fixed price per ton for five years. total amount contracted for is 175 tons from both mine the time fixed is five years. The Nova Scotia has to be expense of adding another 20-stamp to its equipment, to the 6,000-foot aerial tramway, and give a guaranteed e tion. The bullion will be delivered back to the two comp for them to market themselves. The mill should be al handle ore by the first of August.

Fire destroyed the power house at the Nancy Helen i first week of June. The plant, which consisted of a ga ducer plant, a hundred horse-power engine, and the first of a 12-drill compressor, was probably worth about $15,00 work has been in progress for some time, and it is be that fire must have originated from crossed wires. Ne tions were in progress whereby the control of the compan to be turned over to Port Arthur capitalists.

Mr. C. A. O'Connell has taken charge of the Trethewey in place of Mr. George MacNaughton, who succeeded Mr. Loring as manager. Mr. McNaughton is going to Porc after a visit to Nova Scotia.

A strike has been made at the 140-foot level of the Lake north of the shaft, showing a lead about two wide, but of very rich ore indeed. Very few shipment being made from this property at the present time, th grade being conserved until it can be treated at the Scotia mill.

In a bush fire at the Beaver Lake station, South Lorra the British Canadian Company, the power house was b down and the transformers so damaged that they will ha be replaced. This will affect three mines working with tric power, namely, the Wettlaufer, the King George the Alice Lorrain. The accident will not affect the serv Cobalt and Kerr Lake at all.

Kerry mine has now finished pumping out its shaft and commencing to sink the shaft below the 350-foot level. The Consolidated, another lease on Peterson Lake, has commenced operations on Cart Lake. Brydge lease, St. Anthony, Pacific, and Little Nipissing are all working again.

The Meteor Mining Company, a wealthy Pittsburg syndicate is now sinking a shaft on the west side of its claim near the Savage, in an attempt to catch the Savage veins. A considerable amount of work has previously been done by tunnelling into the hill but without result.

The sale of the Cobalt Central has again been postponed and the further date for the offering up of this company is now placed at June 17. All the local debts of the Standard Cobalt, which is controlled by the Cobalt Central, have been paid so that there is some probability that the property will never come to the hammer, but will be worked again by the company under the new management.

Those who are agitating for a Gowganda-Elk Lake railroad are now confident that they will get their desire in spite of the cold reception the Government gave the project a little while ago. It is stated that some New York capitalists are ready and willing to build an electric road if they are given exclusive rights in the territory. Mr. Englehart is going up to Elk Lake to look over the situation early in July.

Excellent results are being obtained at the Miller Lake O'Brien property this year. The ore bodies at the 200-foot and 350-foot level are far better than above, and during the first part of this year the ore reserves have been greatly increased.

NORTHERN ONTARIO AND QUEBEC.

Porcupine, Swastika, Keekeek, and Matachewan.

The fire at the Hollinger was the one event in the history of the new goldfields most likely to delay the inevitable boom. The Hollinger is the company that has so far represented Porcupine abroad, and now that its plant has been burned and its mill operations delayed for six or eight months, there is nothing yet in the camp to take its place.

The compressor at the Hollinger was not damaged and one boiler is available, so that it will be possible to keep work going on a small scale until machinery can be taken in over the railroad to South Porcupine and beyond. The reports from Porcupine are to the effect that the road from South Porcupine to the Hollinger is in such a condition that it is not possible to take heavy machinery over it, and that such transportation will have to be made when the railroad gets in. The T. and N. O. has now promised that there shall be no delay in extending the line from South Porcupine to South Tisdale, and this decision will undoubtedly have important consequences. The best natural townsite in the whole camp is on the sandy plain between the Mattagami and the Hollinger, and here the Hollinger Gold Mines propose to lay out a townsite. No doubt a considerable settlement will grow up here.

Steel on the Porcupine railroad has already been laid to Golden City, Porcupine, and it will be extended to South Porcupine by the middle of June. On July 1st, when the first passenger train will run over the line, it should be well on the way to the Hollinger.

Prospectors coming out of the Keekeek country in Northern Quebec report that while there appears to be no visible gold, the country is excellent for prospecting, and a considerable number of veteran prospectors will be in there this summer.

The route in at present is from Ville Marie to Quinze, 22 miles on a stage, from foot of Quinze Lake to Sturgeon Rapids, 32 miles in a gasoline launch, from Sturgeon Rapids to Gonderal Portage out of the Kenojovis River 22 miles, one mile and quarter and one-quarter of a mile portage into Simonard River, paddle two miles and a half to portage into Wobiskus Lake and thence into Keekeek.

Prospectors have taken full advantage of the easy terms upon which staking can be undertaken in Quebec and lines have been run round probably 100,000 acres to date. Sam LeRoy, the original staker in this country, has a big vein of quartz in the schist on the edge of a bluff near the lake, and J. B. Roy, about two miles and a half back in the bush, has just torn the moss off what appears to be a pegmatite dike about 15 feet wide. Some few men are now going in to do work, and the country looks so promising that good discoveries are quite likely to be made between Keekeek Lake and the Transcontinental before the summer is over.

There is also a rush into the Fort Matachewan country north of Elk Lake, near the Montreal River. No authentic reports have been received from this field yet.

Bewick Moreing & Company, who now control the Rea Mines, have issued a statement that a reef has been struck at the 200-foot level about 15 feet from the shaft. It is 23 inches wide and shows a considerable amount of free gold. At a depth of 240 feet the sections from the shot drill show $19.20 to the ton after free gold had been picked out.

It is stated on excellent authority that the Drummond interests of Montreal have taken over the control of the Jupiter properties in South Porcupine. This will insure efficient development for another Porcupine property. On the next claim to the Jupiter, the vein has been traced on to the Armstrong Booth for a distance of 350 feet. The lead is in places four feet wide and runs on grab assay from the pay streak $42. At 83 feet a diamond drill core contained $20 and $40 assays from the same vein. Mr. E. P. Earle, of the Nipissing, and Mr. Frank Armstrong are interested in this property.

There has been a change in the management of the Swastika mine, an increase of capitalization, and a determination to put the mine on a working basis forthwith. The capital of the company has been increased from $1,000,000 to $2,000,000, and twenty stamps are to be added to the mill, with adequate compressor capacity also. Mr. R. B. Lamb stays as consulting engineer, but Mr. Summerhayes, formerly of the Porcupine Central, takes the place of Mr. Vandergrift as superintendent. Owing to the other good finds made round the Swastika, there is now a considerable amount of speculative interest in this area and a small settlement is rapidly growing up.

The National Porcupine Mines, the first to start operations in the Township of Ogden, have abandoned their option on the Weston properties.

BRITISH COLUMBIA.

A late spring has in some measure retarded progress in the metal mining districts of British Columbia, first cold weather and then much rain having been experienced in many camps. By the end of May, though, weather conditions were generally favourable, with the season's placer gold mining operations fairly entered upon, and wagon roads in lode mining districts, wherever transportation is by horse teams, again hard enough for heavy hauling to be undertaken.

The effects of the general cessation of work in the coal mining districts of eastern British Columbia and western Alberta are not being felt to so great an extent in British Columbia lode mining camps, as it was feared they would be. The prompt action of the British Columbia Copper Company in obtaining a supply of coke for metallurgical purposes from Pennsylvania, followed by the Consolidated Mining and Smelting Company and, at the end of May, by the Granby Company, has resulted in there being no interruption in smelting operations at the respective works of the B. C. Copper and Consolidated companies, and only three weeks' suspension at those of the Granby Company, which last was in some measure influenced as well by the necessity for general overhaul and repair of blast furnaces and accessory plant.

Little or no progress seemed to have been made by the end of May by the Board of Conciliation and Investigation in the

direction of bringing about an agreement between the Western Coal Operators' Association and District No. 18, United Mine Workers of America. For some unexplained reason the board took a recess of three weeks after having visited a number of collieries and taken evidence. Whether or not operators and miners will be any nearer to a settlement when the board shall resume its sittings is not known to the public at the time this is being written. Meanwhile the various collieries are idle and the U. M. W. A. local organization is giving its members a little assistance in the shape of provisions. Opinion outside of those immediately concerned seems to be that there is no present prospect of an agreement being arrived at without further delay.

Cariboo and Cassiar.—Little news is obtainable thus early in the season from the placer mining camps of these districts. Hydraulicking has been fairly started and, there having been an abundant fall of snow through the winter, water is plentiful for gravel sluicing. If the backward spring be not followed by an early hot summer, the season will probably be long and results correspondingly profitable. On the whole there should be a larger total recovery of gold from hydraulic mining operations this year than for several recent years, for some of the larger mines are better equipped and their water supply facilities are larger than in the past.

East Kootenay.—The Sullivan group is now the largest producer of ore in this district, the output of the St. Eugene mine, also operated by the Consolidated M. and S. Company, having fallen off considerably. A comparatively small production is expected from the Society Girl mine, and possibly the Aurora will also send out some ore. There is not likely to be any important change in conditions in the northern part of Fort Steele mining division until after the construction of the Kootenay Central Railway shall have provided railway transportation facilities. Similarly, lode mining in Windermere division will remain at a standstill, so far as production is concerned, although it may be some mine owners will be encouraged to resume development work now that the construction of the railway has been definitely promised and is being proceeded with. Placer mining will be on a small scale on Wild Horse and several other creeks, while on Perry Creek a decided improvement is looked for in connection with the enterprise of some Vancouver men who last year put in a steam shovel to admit of the gravel being handled in larger quantity. Coal mining and coke making in East Kootenay have been stopped for the time being. It was reported about the end of May that an underground fire had necessitated the sealing up of one of the Michel mines of the Crow's Nest Pass Coal Company, but fortunately there had not been any loss of life in connection therewith. The Corbin coal mine, which had an agreement with its men continuing to a later period than that of the larger mines, is now, like the others, not producing coal. Idle miners and coke makers, while not permitted to work themselves, daily see coke from Pennsylvania being hauled over the railway through the Crow's Nest Pass district, on its way to smelting works in Kootenay and Boundary districts.

West Kootenay.—In Ainsworth division, endeavours are being made to extend lode mining operations in the vicinity of the town of Ainsworth, where several properties are being developed. Across the lake, the Blue Bell is still idle. Up the north fork of Kaslo Creek work is being done at three or four mines which from time to time ship ore. The Utica, on Paddy's Peak Mountain, and the Whitewater group, situated nearer the divide between Ainsworth and Slocan divisions, are both being developed with a prospect of again shipping ore if proposed arrangements for a resumption of traffic on the Kaslo & Slocan Railway shall be carried out.

The outlook is favourable for Slocan mining division, especially as regards McGuigan Basin and Four-mile Creek camps. The early construction of a spur from the C. P. R. line from Sandon to Slocan Lake is looked for, a route for this having been surveyed and preparations made for provisioning the m who will be engaged in construction work. The completion this spur will provide railway transportation for zinc ore fr the Lucky Jim mine, near Bear Lake, on the Ainsworth-Slo divide. It will also make practicable the shipment of m silver-lead ore from the Rambler-Cariboo, in McGuigan Ba in which mine developments continue to be most promising, ore has lately been found on the 1,200-foot level, which give another face for ore extraction to add to those alre opened on the 1,050-foot and other levels up to the 700. Ab Cody, conditions seem to be improving, for the finding of other shoot of ore in the Reco has been reported, while velopment on the Noble Five group, Sunset, and Surprise, dicates that all three may be expected to be on the ore-shipp list again before the close of the ensuing summer. N Sandon, the Ruth-Hope, Richmond-Eureka, and Slocan S groups are all being worked, and further production is pected from them. In the vicinity of Three Forks, the Allister has changed hands and the Idaho-Alamo is again ur lease. Near New Denver, the Mollie Hughes is being ta over by a Spokane company, which is expected to work mine on a larger scale than in the past, while the Sweetg is being developed with promise of its making a profitable put of ore. Several of the smaller mines in the mountains New Denver are also having attention this season.

Four-mile Creek camp, or Silverton camp as it is also ca is now the most active in Slocan division, with three im ant mines and two concentrating mills in operation. At Standard mine, development on Nos. 5 and 6 levels has continued. The face of No. 5 is now in milling ore of grade; cross-cutting both ways from the adit has shown width of ore here to be about 85 feet. No. 6 has not yet driven far enough to reach the downward extension of the shoot of galena ore occurring in No. 5, and which is beli to continue to the lower level. Construction of the a tramway to the mill site near the lake shore, about 8,000 away, is in progress, as is also that of the ditch and flum bring water from Four-mile Creek to the place where the compressor plant is to be erected, and thence to the mill Cribbing and excavations for foundations of mill building plant have been completed, and machinery and plant for t way, compressor, and mill equipment are being received. machinery of the new mill the Van-Roi Mining Com started operating on March 15 is running smoothly and re are satisfactory. During the month of April the tonnag ore put through the mill was 3,273 dry tons, the shipping ducts obtained from which were, approximately, 190 ton silver-lead and 230 tons of silver-zinc concentrates. The mer is being shipped to the Consolidated Company's sme at Trail, B.C., and the latter to Bartlesville, Oklahoma, U The Van-Roi mine is looking well, with a large tonnage o blocked out ready for extraction, so that prospects are fa able for a long and continuous mill run under conditions indicate profitable results to the company. The Silv Mines, Limited, operating the Hewitt-Lorna Doone grou also expecting to have an uninterrupted season of produc For several years the development of its mine has been s ily proceeded with, until now there is much ore ready shipment. The higher grade ore, in which freely occur silver and grey copper, the latter also containing much s is sorted out by hand and shipped crude to the smeltery. second-class ore is sent to the Wakefield mill, on Four Creek, for concentration by ordinary water process. One of the Elmore Vacuum Process plant is being put in at mill, to treat the zinc middlings and make a shipping pr to contain 45 per cent. or more of zinc and 100 ounces o ver per ton.

In Slocan City division, the Enterprise and Eastmon Ten-mile Creek; and the Arlington, Ottawa, Meteor, Prince, and Hampton, all on or near Springer Creek, are

l. The Enterprise is under lease to Mr. S. S. Fowler, of ; two shifts of men were employed throughout the win- th the result that shoots of ore were opened from which nts will be made now that the wagon road to the lake is hard enough for use by the freight teams. The East- s owned by the Ellis Silver Mining Company, of Toronto; the winter 15 to 20 men were employed on the pro- and a lower adit was driven. Several shoots of ore passed through and the main orebody opened in the levels was afterwards entered. It is expected that more ll now be shipped than during the corresponding period year. Of recent developments on the several other City properties above mentioned, the most important at on the Meteor, where a shoot of ore was found, 14 to 20 inches in width, and of high grade; from this several cars of ore are expected to be obtained.

General.—Late developments in Rossland mines are more than ordinarily promising. Mines in Nelson division, especially some of those in Sheep Creek camp, are also looking well. Similarly encouraging reports come from some of the mines of the Granby and B. C. Copper companies, in Boundary district. In the Similkameen, the Nickle Plate group is still making excellent returns, and bids fair to long continue to do so. On the Coast favourable reports come regarding the Britannia mines, near Vancouver; the Marble Bay and Cornell mines, Texada Island; and the Hidden Creek copper mine, on Observatory Inlet, under bond to the Granby Company. Space restrictions, however, prevent further notice of these at this time.

GENERAL MINING NEWS.

NOVA SCOTIA.

ey, N.S., June 1.—A new steel ingot record was made . The output was bettered by about 400 tons. The record of 28,142 tons was made in June, 1909.

has started on the foundation of the new nail mill.

ONTARIO.

to, June 3.—In his report on the Hollinger mine made eral Manager Robbins, the details of which the directors king public, Mr. Robbins says the stoppage of mining ns from the fire is not serious, as they have a sufficient of ore developed to keep the mill going for several The principal loss is in the delay which will now occur the mill can be built and put into operation, but even ot a serious matter.

company will now be able to build the complete mill nide plant together and start operations upon a larger an we had previously planned," he says. "All plans g prepared with a view to ultimately treating a large . The new shaft will have four compartments and the ar will be designed to accommodate self-dumping skips. derground work will be so arranged that by means of an d west main cross-cut all of the workings will be con- to the main shaft. The ore will be dumped directly into sher station, and after being put through the coarse it will be elevated to the sampling mill. The reject e sampling mill will be delivered by conveyor to the bins. The probable treatment will consist of coarse g, fine grinding in tube mills, concentration of sulphides tallics which will be treated separately, and cyaniding ntire pulp.

re is little doubt that within a year or so the company e to increase this milling plant to a capacity sufficient from 400 to 500 tons per day. There is in the mine in hbourhood of 200,000 tons of ore sufficiently developed e the company to begin mining upon an extensive scale as the mill is running.

ing the past two months a large part of the under- work has been confined to cross-cutting east and west ain vein and a total of approximately 650 feet of cross- been driven. The result of the work has been highly tory as it has proven that the various veins which par- main vein upon the surface persist below the surface y high values to and below the 100-foot level.

t of the main vein two parallel veins have been proven e 100-foot level. These veins with the mineralized wall rm bodies of payable ore from four to eight feet in Samples taken at random have shown values from $2 to ton.

"East of the main vein a cross-cut has been driven approximately 100 feet to intercept a dome of quartz which outcrops upon the surface. The surface outcropping has been traced for over 300 feet. The cross-cut driven through this vein at the 100-foot level has disclosed the width of the ore body to be 22 feet, carrying values from $9 per ton on the foot wall to $34 per ton on the hanging wall and giving an average of approximately $18 per ton over the entire width of the vein.

"The deepest workings are those on the 200-foot level of the main vein where something over 200 feet of drifting has been accomplished. The vein is from four to 20 feet in width, and the assays are most erratic, varying from $1.60 to $437 per ton. A sample of 16 tons taken from the 200-foot level, about 25 feet north of the winze, was found upon treatment to carry approximately $84 per ton."

Mr. Robbins says the figures are quoted merely as an illustration of the fact that the high values encountered upon the 100-foot level are duplicated upon the 200-foot level.

The report concludes by saying that no disappointments have resulted from either cross-cutting or sinking and the indications are that during the next year work in the unproven ground to the west and to the north of the present workings will add greatly to the intrinsic worth of the mine.

Toronto, June 9.—The by-law to double the capital stock from $1,000,000 to $2,000,000 was unanimously adopted by the shareholders of the Swastika Mining Company at their meeting yesterday. The president stated that his reports from the mine were highly satisfactory. Arrangements have already been made for the underwriting of a large block of the new stock.

The Swastika Company was reported as still in funds, and has $150,000 of the old stock in the treasury.

Toronto, June 2.—Two decisions in cases in which E. J. Townsend, a mining promoter of Sudbury, was defendant, were given yesterday by Chief Justice Falconbridge. A. H. Beath sued Townsend for 10,000 shares of stock in the Golden Rose Mining Company, in which Townsend had a controlling interest, which is in the Temagami district, and asked Beath to assist him in promoting it, promising Beath ten thousand shares. Townsend tried to back out of the agreement, and asked Beath to resign. In giving judgment, His Lordship said that the preponderance of evidence was in Beath's favour and that Townsend's witness was a mere creature. "The defendant was endeavouring to make signals to him in the witness box," said the judge, who gave Beath judgment for 9,000 shares.

The other suit was brought by John F. Black, of Sudbury, respecting the same claim. Black had a small interest in the claim and signed an agreement with Townsend that they would form a company to be known as the "Queen of Sheba Mining Company."

Black claims to have advanced over $3,000 in personal loans to Townsend and for various purposes, such as the purchase of equipment and the selling of stock. He sued for this and $20,000 damages, or 150,000 shares in the Golden Rose Company. Judgment was given for Black with a reference to the Master-in-Ordinary to ascertain the amount due Black.

Cobalt.—The surveys for the 6,000 feet aerial tramway between the Nova Scotia mill and the Crown Reserve, at Cobalt, are now completed, and construction will commence at once. A contract will be let immediately for the installation of 20 additional stamps at the Nova Scotia mill to take care of the 100 tons per day from the Crown Reserve and the 200 tons per day which it is most probable will be trammed to it from another Kerr Lake mine, with which a contract is now being made. This will give the mill 40 stamps and raise the capacity to more than double its present crushing power.

Porcupine, June 1.—The Porcupine branch of the Temiskaming and Northern Ontario Railway will be extended on past the Dome as far as the Pearl Lake district and presumably as far west as the Mattagami. This follows directly in line with the action of the big interests in the Hollinger who have to a greater or less extent been instrumental in securing the decision to carry the road through past their mine.

ALBERTA.

Coleman, Alta., June 6.—Dr. Gordon and Colin Macleod, members of the conciliation board which was to re-convene here to-day to resume the inquiry being made into the dispute between the mine workers and operators in District No. 18, United Mine Workers of America, failed to reach town, and Secretary Carter, the other member of the board, who went to Indianapolis a week ago and who arrived on the west-bound flyer, after waiting until the arrival of the local train from the east, went to Fernie to-night. The executive board of the district held a meeting this afternoon, but nothing was given out as to what action was taken. Vice-President Hayes, of Indianapolis, wired Mr. Carter this afternoon that he was starting for Coleman to-day. M. F. Purcell and William Diamond, of the international board, are here, and Charles Garner will arrive to-morrow. None of the operators have yet arrived, but Manager Wilson and President Stockett are expected this evening.

BRITISH COLUMBIA.

Stewart, June 3.—One of the parties of the Dominion Government Survey Department, who, under Dr. King, the chief astronomer of Canada, are engaged in delineating the Alaskan boundary, arrived here on Sunday, May 21, by the G. T. P. Company's steamer Prince Albert and registered at the Empress Hotel. This party, which consists of the following, Mr. J. H. Mackie, in charge, Messrs. R. G. Evans, J. M. Bates, C. W. Hayward, F. M. Badham, W. Bond, H. McLelland, and B. Dodds, moved out into the field on Tuesday last, and are now encamped at Portland City, two miles from here. Their work will be to carry a series of triangles from the original base extension down to the mouth of the Inlet. Beacons will be established on all points both of the main and secondary triangulations, and a very accurate topographical survey will be made for two miles on either side of the canal. It is estimated that the field work of this portion of the international boundary will occupy three seasons.

The work of delineating the international boundary throughout its length is carried out by alternating parties of Canadian and United States surveyors, and each party is accompanied by a representative from the other nation. The American representative with Mr. Mackie's party has not yet arrived.

The work of the Geological Survey in the Portland Canal district will be continued this year by the Dominion Government. Mr. Connell, who was here last year, is expected fortnight with a party of assistants.

UNITED STATES.

Miami, Ariz.—The Miami plant is running in fine fash Underground work is being carried forward at the rat about 2,000 feet monthly. It is wholly confined to ore-bea ground. Considerable ore is being taken from the stock on the surface, but the bulk of the ore comes from the velopment.

Cripple Creek, Colo., June 3.—From the El Paso min Beacon Hill, company and lessees sent out 131 cars in Ma which the company, mining in the levels just recovered the recession of water, contributed 62 cars, or two cars a

The grade of the ore is about $25 a ton. Several big st are being mined not only by the company, but by lessees. is the banner production from this property to be made number of years, even before the El Paso was flooded. greater portion was mined in the old levels which were clared worked out a number of years ago and which have been producing regularly.

Boston, Mass.—The directors of the Calumet & Hecla declared a quarterly dividend of $6 per share. Three mo ago $6 was declared, a year ago $7. With the payment of dividend just declared the stockholders will have received $5, 450,000 in dividends since the formation of the company

Fairbanks, Alaska, June 5.—A gold strike is reported to been made at Indian Creek, a tributary of the Koyokuk R 300 miles up stream. Pay earth has been struck in two pl Miners are stampeding from here. Gold has also been st on Long Creek, on the north side of the Yukon, opposite M The earth yielded five to fifteen cents to the pan.

MEXICO.

Guadalajara, Mex., June 2.—Milling operations are well der way at the new reduction works of the El Favor Mi Company in the Hostotipaquillo district of Jalisco. The 100-ton plant is running constantly and giving not the slig trouble. At first the launders and tables required adjust in order to produce the proper flow of the heavy "pulp," that has been accomplished, and as soon as the two addit tube mills which are on the ground have been placed in mission, the stamp duty will be increased from four to stamp a day, the present load, to seven tons a stamp daily, perhaps even higher ultimately. At present the product the batteries is first being put through 20-mesh screens, these will be displaced with 8-mesh screens, which will gi much coarser product for concentration over the Wilfley t and Frue vanners. The overflow from the tables will b ground in the tube mills and again pass over the tables t cyanide treatment department.

According to the week's tests, 34½ per cent of the a value of the ore of the El Favor is being saved in the co trates, and slightly better than 50 per cent. of the total a value is being saved in the zinc boxes, making a total reco of 84½ per cent. It is confidently expected that a much hi percentage of saving will be effected as the mill is trimme by steady operation.

The concentrates now are running six kilograms of s to the ton and will furnish in returns at the present cap of the mill a weekly saving of something better than $6,000. saving in the zinc boxes will amount to about $10,000 we The management of El Favor says it is too early yet to pr with safety the ultimate results, as the present tonnag scarcely more than half what it is expected it will be withi next few weeks.

STATISTICS AND RETURNS

TRETHEWEY FOR MAY.

The following is the mill report for the month of May from the Trethewey mine:—

Pounds of concentrates shipped to Thorold, 75,315; No. 1 ore and concentrates shipped to Carnegie, 72,360; ore treated tons 3,577; jig concentrates (pounds), 37,641; table concentrate (pounds), 75,438; totals—75,485 ounces. First-class ore from mine, 35,418 ounces. Total in ounces—109,903. Bullion shipments for month, 1,459 pounds.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending June 9, and those from Jan. 1, 1911, to date:

	June 9. Ore in lbs.	Since Jan. 1. Ore in lbs.
Elger	.....	55,200
Exley	.....	40,000
Esther	.....	6,000
Beaver	.....	716,708
Buffalo	56,590	1,288,010
Cambers Ferland	63,200	575,000
City of Cobalt	.....	493,780
Cobalt Lake	55,980	1,805,250
Cobalt Townsite	.....	480,700
Colonial	.....	42,000
Chiagas	.....	1,873,520
Crown Reserve	49,670	1,208,220
Hargraves	60,000	101,100
Hudson Bay	63,600	438,450
Kerr Lake	.....	1,262,030
King Edward	.....	40,000
La Rose	.....	2,764,870
McKinley-Darragh Savage	64,060	2,685,290
Nipissing	64,920	2,714,910
O'Brien	.....	607,790
Peterson Lake (Little Nip)	.....	58,430
Provincial	.....	40,510
Right of Way	67,680	519,460
Silver Cliff	.....	106,680
Standard	.....	102,813
Temiskaming	.....	775,302
Trethewey	71,400	672,302
Wettlaufer	.....	117,232

The shipments for the week were 617,100 pounds, or 308 tons. The shipments from Jan. 1 to June 9 were 21,693,635 pounds, or 10,8[illegible] tons.

B. C. ORE SHIPMENTS.

Both the Granby mine and the Granby smelter are absent from the ore returns this week, but both are expected to resume operations in a fortnight's time.

The following are the returns of the ore production and movement for the week ended June 3, and for the year to date:

Boundary Shipments.

Mother Lode	6,636	144,685
Rawhide	5,220	84,123

Prompt and Satisfactory Returns

The North American Life is continually receiving from policyholders unsolicited letters like the following, expressive of their appreciation of the treatment accorded them and results attained:

The holder of Policy No 8192 wrote:—
"I appreciate the promptness with which you have remitted the amount due me. I may say that I have nothing but praise for your company for the very satisfactory way in which I have always been treated. Our business relations have been very pleasant and I wish the North American Life the future success it so well merits."

The holder of Policy No. 9205 said:—
"I cannot close matters with the company without expressing my great appreciation of its methods and the very fine manner in which I have been treated by its representatives. In the 20 years of dealing I can recall no single instance in which I have received anything but courtesy and business promptness. I hope to renew relations with the North American soon in respect to my children's insurance."

The Financial Position of the Company is Unexcelled.

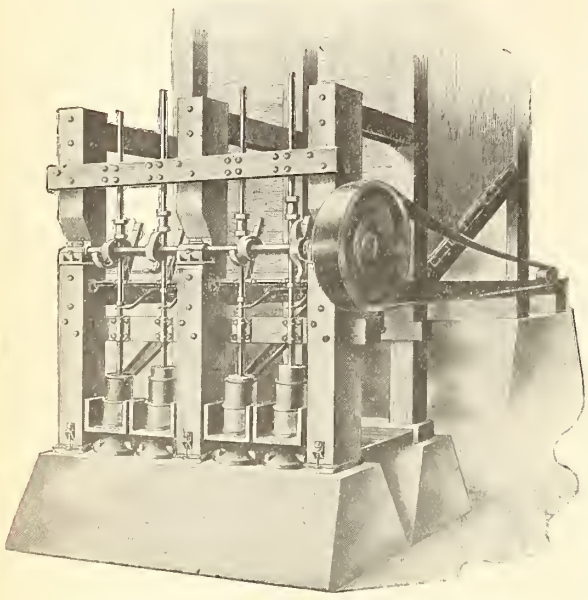
The Nissen Stamp Mil



Nissen Stamp Mill

STAMP. The Nissen Stamp drops with great crushing effect upo a feed comparatively free of the fines caused by preceding impact This causes an actual splash which radiates from the centre of the di carrying the pulp to a circular screen, every aperture in which presen a full opening for the pulp which has already reached size to pa through. As the stamp ascends preparatory for the succeeding blow, partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated type "B" Nissen Mortar

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

PROFESSIONAL DIRECTORY.

e very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining EFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show nerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a nowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing wit a large part of Canada, with many local areas and special subject

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definately the precise area co cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for whi it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mini Institute, etc.

REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map Canada, by G. A. Young and R. W. Brock.

NEW BRUNSWICK and NOVA SCOTIA

1107. Joint Report on the Bituminous or Oil Shales of New Brunswick and Nova Scotia. Also on the Oil Shale Industry of Scotla Part I, Economics, Part II, Geology by R. W. Ells.

QUEBEC

1064. Geology of an area adjoining the east side of Lake Timiskaming, by Morley E. Wilson.

ONTARIO

1091. Memoir No. 1, Geology of the Nipigon Basin, Ontario, by A. W. G. Wilson.

NORTH WEST PROVINCES

1035. Coal Fields of Manitoba, Saskatchewan, Alberta and Eastern British Columbia accompanied by a map, by D. B. Dowling.
1115. Memoir No. 8. The Edmonton Coal Field, Alberta, with maps, by D. B. Dowling.

BRITISH COLUMBIA

1093. Memoir No. 2. Geology and Ore Deposits of Hedley Mining District with maps, by Charles Camsell.
1139. Memoir 11-T Triangulation and Spirit Levelling of Vancouver Island, 1909, by R. H. Chapman.

YUKON and NORTH WEST TERRITORIES

1101. Memoir No. 5, Lewes and Nordenskiold Rivers Coal District, Yukon Territory, by D. D. Cairnes.
1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1006. Report on a traverse through the southern part of the North West Territories from Lac Seul to Cat Lake in 1902, A. W. G. Wilson.

1118. Map 6A. Edmonton. Isobathic lines showing cover over "Clover Bar" coal seam, scale 2640 feet to 1 inch.

BRITISH COLUMBIA

1068. Geological Map (sketch) of the Sheep Creek Mining Camp, West Kootenay, B.C. Scale 1 mile to 1 inch.
1095. Map 1A. Topographical map of Hedley Mining District, Scale 1000 feet to 1 inch.
1096. Map 2A. Geological Map of Hedley Mining District. Scale 1000 feet to 1 inch.
1164. Map 28 A, Sketch map of Portland Canal Mining District.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.
1103. Map 10A. Tantalus Coal Area, Yukon Territory. Scale 2 miles to 1 inch.
1104. Map 11A. Braeburn-Kynocks Coal Area, Yukon Territory. Scale 2 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and econon geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of posta

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners, Chilled Wheels and Castings of all descriptions.

THE
SUDBURY CONSTRUCTION & MACHINERY CO.
LIMITED
SUDBURY :: ONTARIO

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, MONTREAL, for the determination, assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.

The Best New Books for Mining Engineers

Just Issued

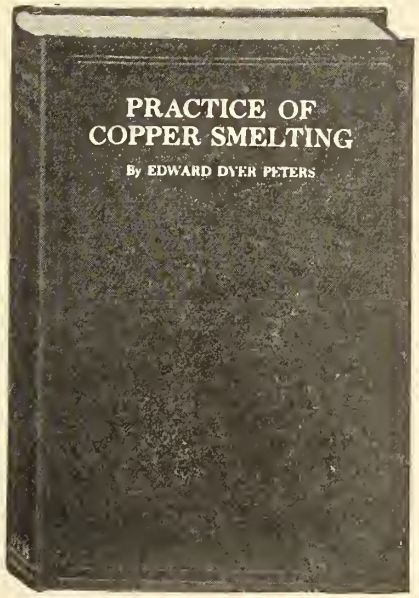
Practice of Copper Smelting

By EDWARD DYER PETERS,
Professor of Metallurgy, Harvard University.

6[illegible] pages, 6x9, illustrated $5.00 (21s.) net, postpaid.

This new work is devoted to the modern, actual methods of Copper Smelting with just enough of the principle to give a clear picture of the reasons for each stage of the operation.

It is the fruit of the author's wide experience and extensive research coupled with the information offered by the principal American Smelting Companies.



Dr. Peter's book presents many important matters which cannot be found elsewhere. It tells of the use of Oil as fuel in reverberatory smelting; pulverized coal in reverberatories; modern converter practice with actual results and costs; the basic lined converter with plans; "Fines"; "Slags"; etc.

It is a companion volume to "Principles of Copper Smelting"

Principles of Copper Smelting

612 pages, 6x9, $5.00 (21s.) net, postpaid.

Modern Copper Smelting

600 pages, 6x9, $5.00 (21s.) net, postpaid.

Mining Books

Underground Surveying

Corrected Edition.

By LOYAL W. TRUMBULL, E.M.

25[illegible] pages, 6x9, illustrated, $3.00 (12s. 6d.) net, postpaid.

Compressed Air

By ELMO G. HARRIS, C.E.
Professor of Civil Engineering, University of Missouri School of Mines.

13[illegible] pages, 6x9, illustrated, $1.50 (6s. 6d.) net, postpaid.

Timbering and Mining

By W. H. STORMS.

3[illegible] pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

Principles of Mining

By H. C. HOOVER.

2[illegible] pages, 6x9, illustrated, $2.50 (10s. 6d.) net, postpaid.

The Cost of Mining

By JAMES RALPH FINLAY.

5 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Tables for The Determination of Minerals

Rock Drills

Design, Construction, Use

By EUSTACE M. WESTON

367 pages, 6x9, illustrations, $4.00 (17s.) net, postpaid.

Describes the leading modern makes of English, Australian and American drills. It assists in choosing machines most suited to particular needs, and using them with the greatest efficiency.

Practical Shaft Sinking

By FRANCIS DONALDSON, M.E.

143 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

The author presents an immense amount of good material in a small space. It is a *timely* volume for mining engineers.

Principles of Metallurgy

By CHARLES H. FULTON,
President and Professor of Metallurgy, South Dakota School of Mines.

536 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

The standard work on this subject. The treatment of the subject is modern. The author presents new ideas, and the style is clear and terse.

Books on Metallurgy

Clennell's Cyanide Handbook

By J. E. CLENNELL.

526 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Ore Dressing

By ROBERT H. RICHARDS,
Professor of Mining and Metallurgy, Massachusetts Institute of Technology.

Four volumes, 2,000 pages, 6x9, illustrated, per set, $20.00 (£4 4s.) per volume, $5.00 (21s.) net, postpaid.

Elementary Crystallography

By W. S. BAYLEY, PH.D.,
Associate Professor of Mineralogy and Economic Geology, University of Illinois.

236 pages, 6x9, 300 illustrations, $2.00 (8s. 6d.) net, postpaid.

Metallurgy of Lead

and the Desilverization of Base Bullion

By H. O. HOFMAN.

600 pages, 6x9, illustrated, $6.00 (25s.) net, postpaid.

Metallurgical Calculations

By JOS. W. RICHARDS.

Three volumes, each volume over 200 pages, 6x9, $2.00 (8s. 6d.) net, postpaid per volume.

High-Grade Transits

Keuffel and Esser Transit No. 5165

This transit is designed to meet the requirements of the mining engineer. It is a sturdy instrument and will stand the roughest kind of work. It weighs 10¼ lbs., telescope 9 ins., object glass 1 in., vertical limb 4 ins., horizontal limb 5½ ins. All graduations on solid silver. Four leveling screws of solid German silver.

Instrument complete with tripod - **$195.50**

Instruments of this make are recognized all over America to be of the highest standard of manufacture. Every instrument carries with it our unqualified guarantee.

Another value that will interest surveyors is our Railroad Dumpy Level at **$80.**

And you'll find here a splendid selection of engineers' chains, steel and cloth tapes, tracing linen, etc., of the most dependable kinds.

Optical Section, Second Floor.

THE T. EATON Co LIMITED
TORONTO CANADA

BRITISH COLUMBIA

The Mineral Province of Canada

nas oduced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,(5,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the ead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has een even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dom ion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crow Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

ANNOUNCEMENT

THE CANADIAN MININC JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

ECONOMY OF STEAM
IN
THE POWER HOUSE

The Condenser is as old as the steam engine itself, but has until very recently received far less consideration and has been treated as an anxillary, the reliable working and efficiency of which had but little bearing upon the economy of the plant as a whole.

With the advent of the steam turbine and the demand for higher economies, the importance of the condensing apparatus has become more clearly apparent, and it now holds its rightful place as one of the principal parts of the steam plant.

Our independent air pump and jet cone condensing apparatus will save from 20 to 30 per cent. in steam when applied to non-condensing steam engines, or will give an increase of power of corresponding amount. It can be attached readily and placed in the most convenient place.

We get the best results by designing and building condensing apparatus specially to suit the conditions of operation.

Renold Patent Silent Chains

What Users Think

MONTREAL, Feb. 8, 1909.

Messrs. Jones & Glassco, Montreal.

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your enquiry of Jan. 30th, I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.

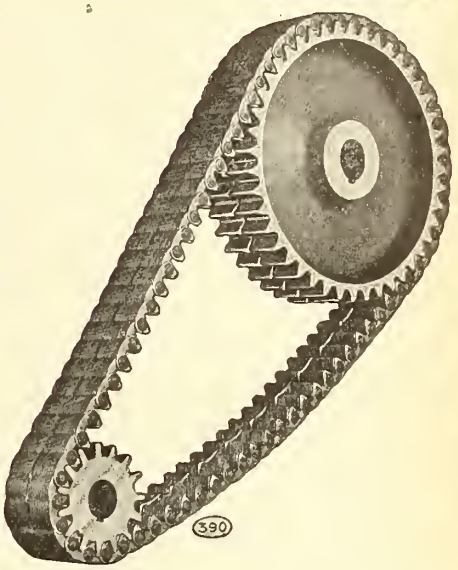
Our first drive was installed to replace a 12 in. belt which was giving us trouble on account of short centres; this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing; this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears and this has been so successful that we are now installing two more similar drives.

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drive in operation.

—The above comes from one of the largest manufacturers in Montreal and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.



Write for particulars.

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

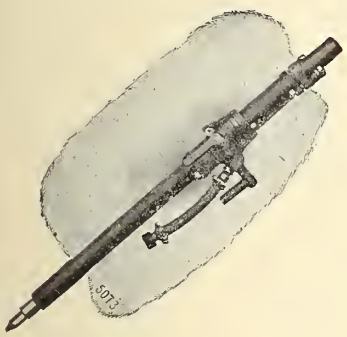
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The
PATERSON MFG. Co., Limited
Montreal, Toronto, Winnipeg, Vancouver, St. John, N.B. Halifax, N.S.

TELESCOPE FEED

HAMMER DRILLS



Probably no machine, from which such great results are expected and upon which so much depends, receives as much abuse and as little attention as the rock drill.

To successfully take the place of the rock drill, the hammer drill mustbe of such construction as to withstand a large part of the same kind of abuse.

The design of the Rand "BC-11" Telescope Feed Hammer Drill more nearly approaches rock drill construction than anything hitherto offered. The stroke of the piston is positive and powerful. There is no fluttering or sticking of the piston, it cannot reverse until it has completed a long full powerful swinging blow with every oscillation of the valve.

This new tool is worth a trial.

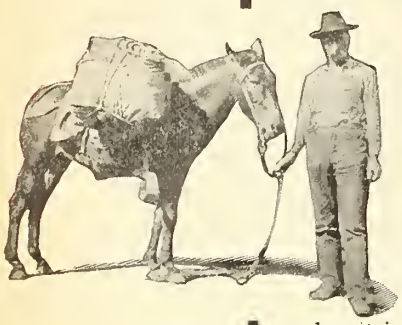
Going to the Hills?



Whether for pleasure or profit, you are sure to run across ore that will excite your curiosity. You may pick up a piece here, or a friend may hand you a sample there—you want to know what is in it—what it is worth. So why not take a

Way's Pocket Smelter

with you. You will find testing by **Way's Process** full of absorbing interest. And you can make tests for any ore of commercial value at a cost of but five cents—and ten minutes of your time. And a test that is accurate enough for all practical purposes. Field Outfits weigh but five lbs. Contained in canvas and leather case for carrying—with shoulder strap. Let us tell you of this, and the other outfits.

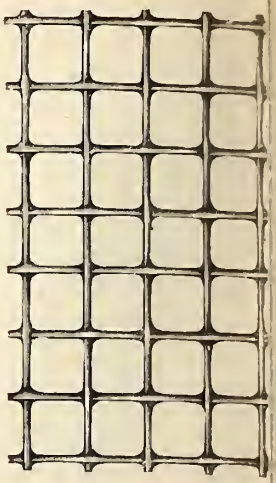
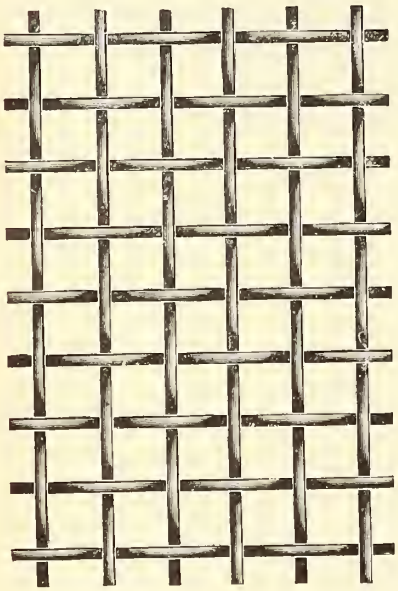
GREENING'S PERFORATED SHEET STEEL MINING SCREENS





Having been for a great many years in the business of manufacturing Perforated Metals, and operating our own die-making plant, we have accumulated a large assortment of different shapes and sizes. Consequently we are in an excellent position to fill promptly any of your perforated metal requirements on short notice. By sending us specifications of size of hole, quanti size and thickness of sheets and kind of metal you require, we ca give you quotations by return mail. Our Perforated Metal Catal should be in every mine office as the cuts by which it is illustrate enable a superintendent to send in rush orders with the minimum difficulty and with the assurance that they will be accurately filled.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

Nissen Stamp Mill

The Nissen Stamp Mill

STAMP. The Nissen Stamp drops with great crushing effect upon a feed comparatively free of the fines caused by preceding impacts. This causes an actual splash which radiates from the centre of the die carrying the pulp to a circular screen, every aperture in which presents a full opening for the pulp which has already reached size to pass through. As the stamp ascends preparatory for the succeeding blow, a partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated type "B" Nissen Mortar.

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

OPPORTUNITIES.

At risk of wearying our readers we intend once again to draw attention to little-known fields for mining investment in Canada.

In our last issue we referred to the beneficial effect that certain prosperous mining camps have had upon the country generally. There is, however, another side to the subject. The excitement that attends the development of new mining regions is apt to give to outsiders the impression that these regions are the only profitable channels of investment. To many Englishmen, Americans, and Europeans. Cobalt and Porcupine embrace all of Canada that is worth while looking at. This is one of the misconceptions that must be patiently corrected. And it is for this purpose that we are guilty of reiterating the following facts.

We shall preface what is to be said by the remark that the most numerous chances for profitable outlay of money do not lie in camps that are being boomed. The mere fact that a mining camp happens to be the focal point of public interest creates conditions that militate against equitable terms of purchase and operation. This is so obviously a truism that it requires no demonstration.

On the other hand, deposits of such minerals as iron pyrites, scheelite, chalcopyrite, pyrolusite, graphite, gypsum, barite, magnesite, and so on, are lying undeveloped in many parts of eastern and western Canada. Not a few of these deposits can be easily and quickly proven. Many of them are already known to be commercially workable. The growth of our own markets alone demands that they be exploited. The possibilities of the foreign markets lend additional inducement.

Even more attractive are the chances that offer in the older gold fields. Study of Provincial and Federal reports shows that some of the gold discoveries of from thirty to fifty years ago were as rich as anything of recent times. But not until within the memory of this generation have circumstances been such as to encourage a large measure of enthusiasm. The limiting conditions were the lack of means of communication, and the absence of adequate media of information.

Times have changed. It is now possible to work to advantage all kinds of mineral deposits throughout the length and breadth of the Dominion. To the disappointed searcher for cheap bonanzas in Porcupine we would suggest that he read up the mining history, not only of Ontario, but also of British Columbia, Quebec, and Nova Scotia; and that he take steps to ascertain for himself the merits of forgotten districts.

THE SAMPLING OF COAL IN THE MINE.

Under this caption the United States Bureau of Mines has brought out its first technical paper. The subject is one of vast commercial import, and, hence, of high technical interest. Dr. Joseph A. Holmes, the Director of the Bureau, is the author. The purpose of the paper is to describe the methods followed by the Bureau and the Survey in taking commercially representative samples of beds of coal.

After describing an ingenious and compact mine sampling kit, Dr. Holmes gives preliminary details, and proceeds to describe the method of sampling. Much emphasis is laid upon the necessity of cleaning thoroughly the face to be sampled, and of including in the sample all material that is usually comprised in the daily shipments. Only such material as is ordinarily discarded by the miner should be omitted.

Specific instructions follow as to the precise method of sampling a working face. First, the floor is to be cleaned and the sampling cloth spread close to the face. Next, a perpendicular cut 2 inches deep and 6 inches wide, or 3 inches deep and 4 inches wide if coal be soft, is made from roof to floor down the side of a foot-wide cut previously made. The cut should be uniform in width and depth. Enough coal should be chipped off to make a sample weighing at least six pounds for each foot of the width of the seam.

The sample is put through a ½-inch or ⅜-inch screen, and is mixed and quartered as usual. A suitable sample can is then filled completely and sealed. It is important that the entire series of operations be carried on in the mine. If this precaution be disregarded, errors will creep in. Exposing the coal to the outside atmosphere is found to introduce abnormal factors.

Investigation of the loss of volatile constituents when coal is freshly mined, and knowledge of the effects of weathering upon many fuels, have led the Bureau to devise and distribute exceedingly complete blank forms whereupon is transcribed the history of any given sample. These forms embrace details of the physical features of the mine, of the equipment, of the humidity report, of the explosives used, of general mining and marketing conditions, and of the sample itself. Thus the sample and the final analysis are given a value that they could not otherwise have. And herein is the point of the whole matter. There are available thousands of analyses of Canadian coals, analyses that are either misleading or meaningless because of the fact that there is no authentic record of how, and why, and when they were taken. Modern commercial engineering will not tolerate that slipshod professional work. Time was when laboratory results were accepted at their face value. Now, however, it is being more and more widely recognized, even in lay circles, that sampling is one of the most difficult and responsible tasks, and that few men are temperamentally fitted to do it fairly. But, no matter with what skill the sample may be taken, it cannot be accepted commercially without full data as to every item of its history.

SCIENCE vs. GREEK.

In many respects the educational systems of to-day are medieval. Of the number of compulsory subjects of study that are inflicted upon our youth, many have no relation either to real life or to real culture. This fact is being impressed more and more deeply upon British educationists. No one has put the case more cogently than has Sir Rae Lankester. Writing in "The Nineteenth Century and After," Sir Rae, whilst disclaiming any desire to see natural science take exclusive possession of the educational field, condemns strongly the domination of that field by Latin and Greek. The whole system of instruction and of competitive examination he scores as being an injurious perversion. He declares that "the school-teaching of the old knowledge has become sadly unreal, perfunctory, and slow . . . . The husk of it is mistaken for the kernel, the letter for the spirit, mere dexterity in verbal acrobatics for true learning and sound mental discipline. We can in the future retain some study of ancient history and literature, and even one of the classical languages—namely, Latin—while giving serious our attention to the new knowledge—the natural science of our present Renaissance."

This pronouncement is all the more interesting as Sir Rae was, in his youth, a product of the system that he criticizes. At St. Paul's he was the head-boy and prize-winner in successive classes of the Latin and Greek curriculum.

The cardinal point of the article is presented thus: "It is the business of the 'educator' to ascertain the various degrees and kinds of 'educability' in the young and to adapt the course of education administered to them to their varying aptitudes." The youth of to-day must not be over-burdened with useless information. But his intelligence must be so trained as to open for him all desired branches of knowledge. The effect of proper study of the sciences is lasting and practically beneficent; the effect of unnecessary study of the dead languages is entirely mischievous.

Amongst the sciences to be taught, Sir Rae includes chemistry and geology. He recommends that these subjects be carried farthest. This is something for Canadian educationists to take to heart. A sweeping change must soon be brought about. Our young men should learn at school and at college more about nature, more about commerce, and less about the amours of heathen gods.

Each reading man can acquire a knowledge of the humanities after his formal education is complete. Every Canadian citizen should be possessed of a sound grasp of the fundaments of natural science.

GOVERNMENT DRILLING IN NOVA SCOTIA.

The Government of Nova Scotia adopts the liberal policy of keeping and operating seven core drills for the benefit of the mining community. During the year 1910 five drills, of which three were diamond drills and two calyx drills, were kept in commission. The total footage drilled was 5,222 feet. Of this footage, 4,50[illegible] feet were done by diamond drill. In all fifteen holes were sunk, and in every case coal was the mineral sought. The strata drilled included sandstones, shales, conglomerates, clays, and grits of many varying degrees of hardness, and of every kind of texture.

The average cost per foot of diamond drilling is reported at 93 cents; whilst the corresponding figure for the calyx is $1.44. The deepest hole bored was sunk with a 2-inch diamond drill. The depth attained in this instance was 1,217 feet; the cost per foot, 72 cents; the highest rate of boring per hour, 5 feet 3 inches; and the average footage per hour 1.2 feet. It is interesting to compare these figures with the performance of a 6-inch calyx. The calyx hole was sunk to 566 feet. The highest rate of boring per hour was 6 feet 4 inches; the average footage per hour 1.27 feet; and the cost per foot $1.44.

It is not intended to institute comparisons between the two types of drills. The figures above are quoted merely because of their intrinsic interest. Incidentally it is noteworthy that the coal operators are the only persons securing the drills. It is surely worth while for a few of the gold-mine operators to put in a claim. Under proper control the diamond drill, which probably would do better work in the gold measures, could be utilized to great advantage.

DEEP WELLS.

The deepest well ever bored was started nineteen years ago near Rybuick, Upper Silesia, Germany. It was completed in one year and a half. The depth attained was 6,572 feet, and the diameter was from 3.6 inches to 2.7 inches. The total cost was $18,241. The mineral sought was coal.

Another well, probably the fourth deepest, was drilled near Leipsic, Germany. The diameter of the core in this case was 11 inches to 1.3 inches. The total depth was 5,735 feet, and the cost $53,076. The object sought was also coal.

The second deepest well was completed in 1905, after nine months' work. This was a diamond drill hole, sunk near Johannesburg. The depth reached was 5,752 feet, the core 2 to 1⅜ inches.

A remarkable well, the deepest ever drilled with a cable, was sunk near West Elizabeth, Pa. With a 10 inch to 6¼-inch core, this well attained a depth of 5,575 feet.

Very deep wells, in some instances exceeding 5,000 feet, have been drilled in Australia for water. From one well in Queensland a flow of 1,600,000 gallons of water a day, having a temperature of 202 deg. F., was obtained.

TITLES AND THINGS.

In the eyes of Canadians nothing could well detract more from the dignity of Coronation week than the announcement that the organizer of the Cement Merger had been decorated with a Knighthood. Of itself this might be a matter of congratulation. But when our most eminent economist, our leading educationist, and several other distinguished public men are awarded trifling honours; and upon a young man, whose business reputation is not yet cleared of a serious stain, a knighthood is bestowed, it is time to call a halt.

Knighthood and other forms of royal recognition are the rewards of outstanding service to the public. Sir Max Aitken has performed no such service. His claim to distinction is based upon a remarkable facility in organizing mergers, in persuading the public to buy securities at an enhanced price, and in reserving for himself a disproportionate share of the spoil. His spectacular irruption into English politics gave him advertisement. More advertisement, of a different nature, was given him when Sir Sandford Fleming accused him publicly of unhallowed practises in the realms of high finance. And now his name stands upon the list of those whom our King delights to honour! It is to laugh, or to weep!

"DATA."

We rise again to defend a cruelly bullied and maltreated word. "Data" is the plural form of "datum." In no circumstances is it permissible to use the word in the singular.

The writers of mining reports constantly err in this respect. An example will soon have to be made of someone. Condign punishment should be meted out to all and sundry who misuse a defenceless but extremely useful word.

EDITORIAL NOTES.

The prestige of Sir Max Aitkin has apparently suffered no abatement. Knighthood followed hard upon the heels of what promised to be a lively scandal in cement. It will be interesting if the critics of Sir Max put a daub or two upon his fresh title.

Somewhere about 11,000 sovereigns, representing $55,000 worth of gold, have been minted recently at Ottawa. The metal came from the Hollinger mill.

Practical encouragement has been offered in the shape of $5,000, for the production of safe and satisfactory types of electric lamps for colliery work. Full particulars may be obtained from the Department of External Affairs, Ottawa.

It has been stated that, if working costs remain as at present on the Rand, the end of profitable mining will be reached at or before a vertical depth of 5,000 feet. Future economies will affect new mines rather than established concerns. In six years total average costs per ton have been reduced from 29s. to 21.5s., but average profits have fallen from 6.03s. to 5.85s. The probable net profit from ore extracted at a depth of 5,000 feet is estimated at 1.575s.

The output of gold from Transvaal gold mines during May exceeded all previous monthly records. It amounted to the magnificent total of 685,951 ounces, which, interpreted in terms of our own currency, means nearly fourteen million dollars. Facts like this should squash effectually the purveyors of torrid atmosphere who compare Porcupine with the Rand. There is a long hard row to hoe yet.

BOOK REVIEW.

THE DREDGING OF GOLD PLACERS, BY JOHN ERNEST HODGSON, F.R.G.S., MANAGER ASHANTI RIVERS AND CONCESSIONS, LTD. — 65 PAGES — ILLUSTRATED— PRICE, $1.50 NET — PUBLISHED BY SIR ISAAC PITMAN & SONS, LTD., No. 1 AMEN CORNER, LONDON, E.C., 1911.

There is a marked paucity of literature on dredging for gold. We therefore feel inclined to welcome any addition to the meagre list of books dealing with this subject.

Mr. Hodgson's book purports to be "a practical guide for company directors, property managers, prospectors, and those of the investing public who have acquired, or think of acquiring, a share interest in a gold-dredging concern." This, we fear, is too large a claim. The book is an interesting, but extremely one-sided, essay. It is tenuous, incomplete, and typically English.

By that last phrase we mean that the author exhibits the characteristically lofty British disregard of practice other than his own. His references to the Yukon and to California are meagre and insufficient. He is satisfied that English dredging represents the last word in modern placer-working. In this, of course, he is hopelessly wrong. There is a great gulf fixed between the adaptable, efficient, and highly sensitive American dredge (or "dredger"), and the clumsy Engdish and German machines. Also, there is decided difference between working costs on this continent and those obtaining in other countries.

Yet, despite its manifest faults, and in some instances because of them, Mr. Hodgson's book is edifying. It reads well, it is consecutive, it is clearly printed and well illustrated.

Personal and General

Mr. A. B. Willmott, mining engineer, Lumsden Building, Toronto, has recently completed examinations of mine properties near Fort Frances, Ont., and near the Maine border, in Quebec.

Mr. H. H. Sutherland, formerly of Nova Scotia, has taken an office in the new Standard Bank Building, corner of Jordan and King Streets, Toronto.

Mr. Myles Flynn, of New York, is in London, F land.

Mr. George R. Rogers, mining engineer, of Toronto now in Porcupine at the Prince George Hotel. Rogers is conducting several examinations and will in Porcupine for some weeks. One of his mission to investigate probable methods of ore treatment.

Mr. J. B. Tyrrell has returned from the Swas region.

Mr. R. B. Lamb, consulting engineer to the Swas Mining Company, is in Toronto.

Mr. Kent Johnston, of London, England, is at Albany Club, Toronto.

Mr. Stanley Leeky, of G. G. S. Lindsey and C pany, Toronto, has returned for a visit to western tario.

Mr. Clifford Smith, mining engineer, of Brockv Ont., is in Toronto.

Mr. Eugene Coste is moving to Calgary, Alberta.

For the reconstructed Jupiter Mining Company, P cupine, in which the Messrs. Drummond, of Montr have a heavy interest, Mr. J. H. Rattray has been pointed manager and Mr. R. W. Brigstocke consult engineer.

Mr. A. H. Brown, of Cobalt, has lately been visit mining camps in the Boundary district of British lumbia.

Mr. R. H. Chapman, of Washington, D.C., one of topographers of the United States Geological Surv will again do topographical survey work on Vancou Island, B.C., for the Canada Geological Survey. T will be Mr. Chapman's third field season in that par British Columbia.

Prof. Francis A. Thomson, head of the Department Mining Engineering, State College of Washing Pullman, Wash., U.S.A., with a class of senior stude in mining engineering and metallurgy, has been visit mines and smelteries in Boundary and Trail Cr districts, B.C.

Mr. James Anderson, manager of the Ruth-H group and other silver-lead mines in West Kootenay, returned to Kaslo, B.C., from a visit to England a Scotland.

Mr. Norman Fraser has resigned the position superintendent of the Crow's Nest Pass Coal Compan Michel colliery to accept that of manager of the G man Development Company's coal mining property Brazeau, Alberta.

Mr. G. E. Farish, of New York City, is stated to h been appointed manager of the Summit mining p perty, in Sheep Creek camp, Nelson mining divisi control of which is stated to have been purchased lat by Montreal and New York men.

Mr. W. G. Norrie, of Mr. Andrew G. Larson's offi Vancouver, B.C., will superintend mining operati at the Ikeda mine, Moresby Island, of the Queen Ch lotte group, under Mr. Larson, who is the owning co pany's consulting engineer.

Mr. W. B. Thompson, of the firm of Thompson, Tov & Co., New York City, has been appointed a direc of the British Columbia Copper Company, Ltd., in s cession to Col. J. C. Reiff, deceased. Mr. Thompson connected with several large mining companies oper ing in North America, among others as president of t Inspiration Copper Company, of which Mr. W. Aldridge, formerly managing director of the Cons dated Mining and Smelting Company of Canada, Lt is now managing director, and which owns a large c per mine in Arizona.

STANDARD METHOD OF WELL DRILLING.*

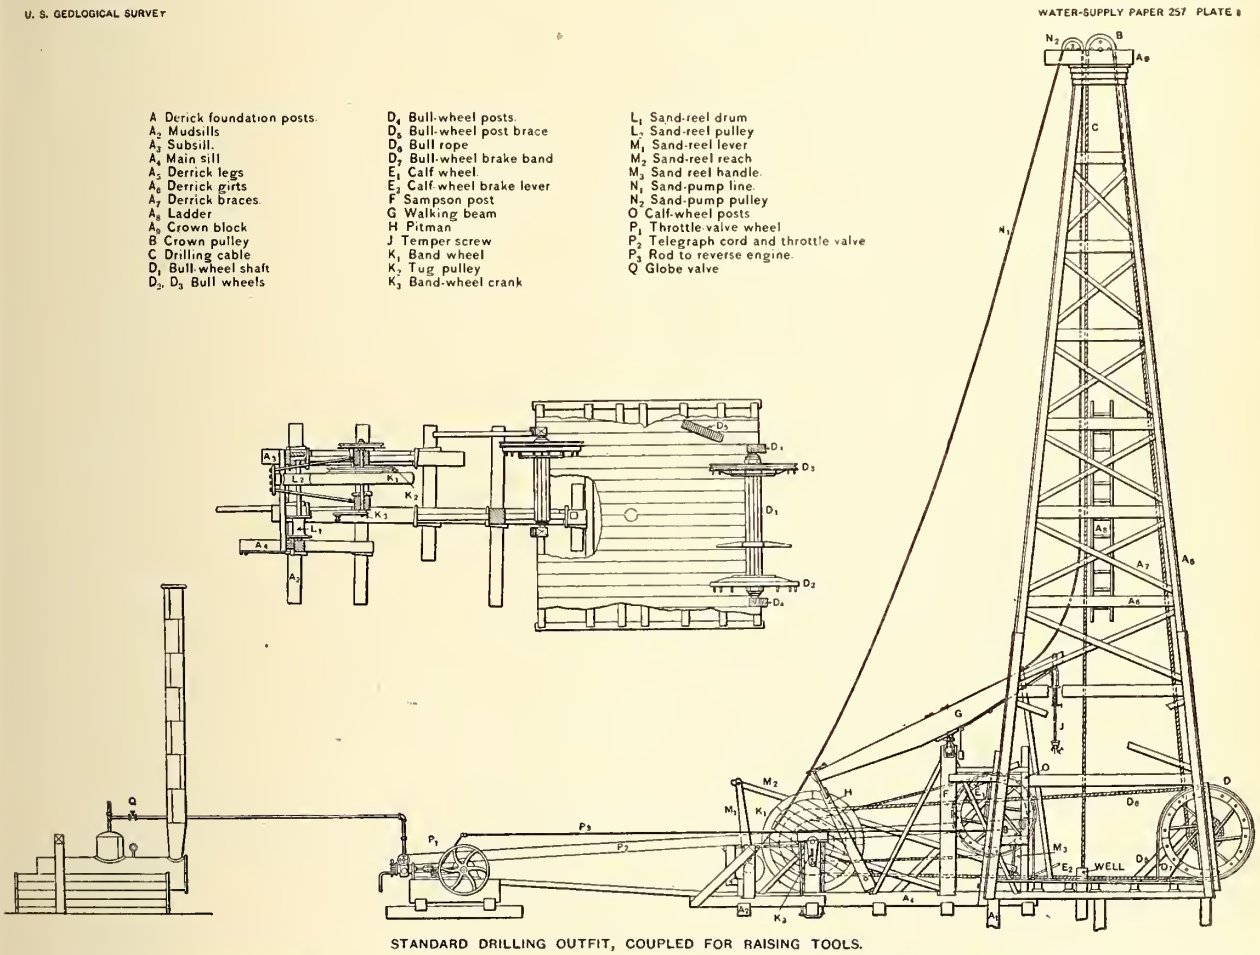
By Isaiah Bowman.

The largest and deepest wells put down art those sunk to obtain oil, and the heavy standard outfit, now so extensively used, acquired its essential characteristics in the development of the oil industry in Pennsylvania. In overcoming the difficulties encountered in drilling deep holes the tools have been enlarged and the several parts of the outfit have been modified and improved until the size and weight of the tools and the ease with which they are handled surprise those unfamiliar with this class of machinery.

Standard outfits differ little in essential features, but hardly two can be found alike in every detail; the slight variations that exist are due not to some fancy or whim of the driller, but to the need for adapting the outfit to special conditions.

The derrick consists of four legs, steadied by girts and braces and surmounted by a crown block. In this block is set the crown pulley, over which the drilling cable passes. A ladder extending up one side of the derrick provides access to the crown block. The weight of the derrick rests on foundation posts, which are set deep in the ground to render the structure firm.

At one side of the derrick are the bull wheels. This part of the rig consists of a reel, on which the drilling cable is wound, at each end of which is a wheel, usually built up of wooden arms and segments, fastened together with wooden pins. These parts are known to the trade as arms, cants, and handles. The whole is sent firmly into the bull-wheel posts and strengthened by the bull-wheel post brace. The wheel at the farther



STANDARD DRILLING OUTFIT, COUPLED FOR RAISING TOOLS.

Outfit—Rig.

The most noticeable part of a standard outfit is the derrick, a pyramidal framework, 30 to 90 feet high, erected over the well. In summer the derrick is usually left open except on one side, which is boarded in to form a shed for storing tools and workmen's clothes and to protect the forge — a part of the outfit that is in more or less constant use. In winter the lower part of the derrick is temporarily closed to protect the workmen. In a new territory drillers sometimes close the derrick, even in summer, to keep the results of the drilling secret.

*Abstract from bulletin issued by the U. S. Geological Survey.

end of the reel in the illustration (Pd. I, D_3) is grooved to receive the bull rope, which acts as a belt to operate the reel. The brake by which the reel is controlled passes over the near wheel of the illustration and is controlled by a lever. In the early rigs this brake consisted of rope or a piece of old rubber belting. When the tools were lowered the rope would burn and smoke, and the rubber would emit a very disagreeable odor. In present rigs an iron brake band is used.

In the California style of standard rig a second reel, known as the calf wheel, is placed on the side of the derrick opposite the bull wheels. It carries a cable that is used in lowering and in pulling casing. It is claimed that in deep drilling it saves much time as it

obviates the necessity of disconnecting the tools from the drilling cable for these operations.

Opposite the bull wheels is the samson post, usually about 14 feet long. This post is strongly braced and supports the walking beam. The derrick end of this beam is directly over the well and carries the temper screw to which the tools are fastened and by which they are fed downward. The other end of the beam carries a pitman, which is connected with the crank of the jack or band wheel by a wrist pin. This band wheel is supported on jack posts and transmits power to the several parts of the rig — to the walking beam by means of crank and pitman, and to the bull wheels through the tug wheel and bull rope. In the California rig the calf wheel is also operated by the band wheel through a second tug wheel and rope belt. The operation of the calf wheel is usually controlled by a lever and clutch, and the bull wheels are usually thrown in or out of gear by putting on or removing the bull rope.

The sand reel is just behind the band wheel and is operated by the latter through a friction pulley. This reel is mounted on a knuckle post and is controlled from within the derrick by means of the sand-line pulley, and, as its name indicates, it is used in handling the sand bucket or bailer.

The part of the rig that extends beyond the derrick rests on mud sills, which are usually sunk in trenches and have gains cut in them to receive the subsills and main sill, and the whole foundation is carefully levelled up and firmly keyed together.

The headache post, also called the life-preserver, is a comparatively recent improvement. As its name implies, its purpose is to save the driller from injury to the head if the wrist pin breaks or the pitman is thrown out of adjustment while drilling, as it prevents the derrick end of the walking beam from dropping and injuring anyone who may be beneath it. This post is usually a piece of heavy timber set on the main sill directly under the walking beam, so that in case of accident the walking beam can fall only a few inches. It is also useful when repairs are necessary to the pitman or the band wheel and crank, for a block may then be placed between the headache post and the walking beam, and the pitman relieved of its weight and slipped from the wrist pin without making it necessary to disconnect the tools from the temper screw.

Variations in the size of the parts of a rig depend on the amount and difficulty of the work to be performed. At Bradford, Pa., where few of the oil wells are more than 2,000 feet deep, the derricks are 72 feet in height; at Kittanning, where wells between 2,000 and 3,000 feet deep are common, the derricks are 82 feet high. An increase in the length and weight of the tools used is always accompanied by an increase in the size and strength of the derrick. The stems alone of the drills used at Kittanning are 39 to 42 feet long, and the sand buckets used with some outfits are 60 feet long. The walking beam used in this field is also larger than usual, being 24 feet long, as compared with 16 feet at Bradford. At Kittanning the hemp drill rope is 2¼ inches in diameter; in the Bradford field it is 1¼ to 1½ inches. These figures show the structural changes that follow a change in the amount of work to be done.

For a 72-foot derrick about 13,000 board feet of lumber are required for the framework and wheels, and, if the derrick is closed in, about 3,000 feet of siding. In places where it is difficult to get skilled rig builders, as in the Philippines or in newly developed oil regions, bolted wood derricks are very serviceable. The timbers are all framed and distinctly marked so that the derrick can be easily erected.

Steel derricks have not found much favour, though they are easily taken down, transported, and set up again, and offer slight resistance to the wind. The driller objects to them chiefly because of the delay and expense entailed by the necessity of sending to the supply house for repairs when a part becomes broken or twisted, whereas repairs on wooden derricks can be made quickly by unskilled labour and with cheap material. The loosening of bolts — a serious defect of the steel derrick — has been overcome, at the expense of considerable additional time in erection, by using a guard nut on each bolt.

A bolted wood or steel derrick may be set up in two or three days. Three or four skilled workmen can put up an ordinary nailed derrick in from three to five days, the time depending on the size of the rig and the quality and accessibility of the lumber; but after a nailed derrick has been used for two or three jobs it becomes too badly worn and racked to be set up again.

Where oil wells are drilled close together, or where on account of trees or buildings, there is limited space for operation, a rig with a short walking beam is sometimes used. This rig occupies a plot about 20 by 30 feet in size, and is very compact and serviceable.

Engine and Boiler.

Beyond the derrick and other parts of the rig is the engine, which furnishes power to the band wheel by a belt. Steam power is almost universally used and is supplied by a boiler placed a short distance from the engine. The throttle of the engine is controlled from the derrick by a double line of telegraph wire passing over small pulley wheels, and the reverse lever is operated by a rod that extends from the engine into the derrick.

The boiler used in connection with the standard rig ranges from 15 to 40 horsepower and the engine from 12 to 30 horsepower. Boilers are of two general types —horizontal and upright. The horizontal — called the oil-country boiler (see Pl. I. Q)—is in most general use. The upright boiler differs from the horizontal mainly in shape, but is smaller than the oil-country boiler, and is more easily moved and set up. It is used in some parts of the California fields, where it is closed in with natural adobe instead of brick. In many oil and gas fields either oil or gas may be obtained from other wells for fuel under the boiler.

Engines of various styles are used even in the same locality, but all are usually so fitted that they can be controlled from the derrick and are otherwise adapted to the particular needs of the work.

Steam may be supplied to the pump through insulated pipe led from the boiler, or a gasoline engine may be set up near the pump. Gasoline engines are used with many outfits in Indiana and Pennsylvania and are said to be more economical and to require less care than steam.

Where there is no near-by well or stream from which a water supply can be obtained, a water well is sunk by means of the outfit before work on the oil well can be begun. The water well is usually put down immediately beneath the walking beam, about 3 feet back from the point where the deep hole will be drilled, in order to lessen the labour of drilling it and

pumping the required water. Water for drilling well and for the boiler is hauled from the nearest lable source. After a water supply has been obed a pump is so installed that it can be connected the walking beam, by which it is operated when wa er is needed.

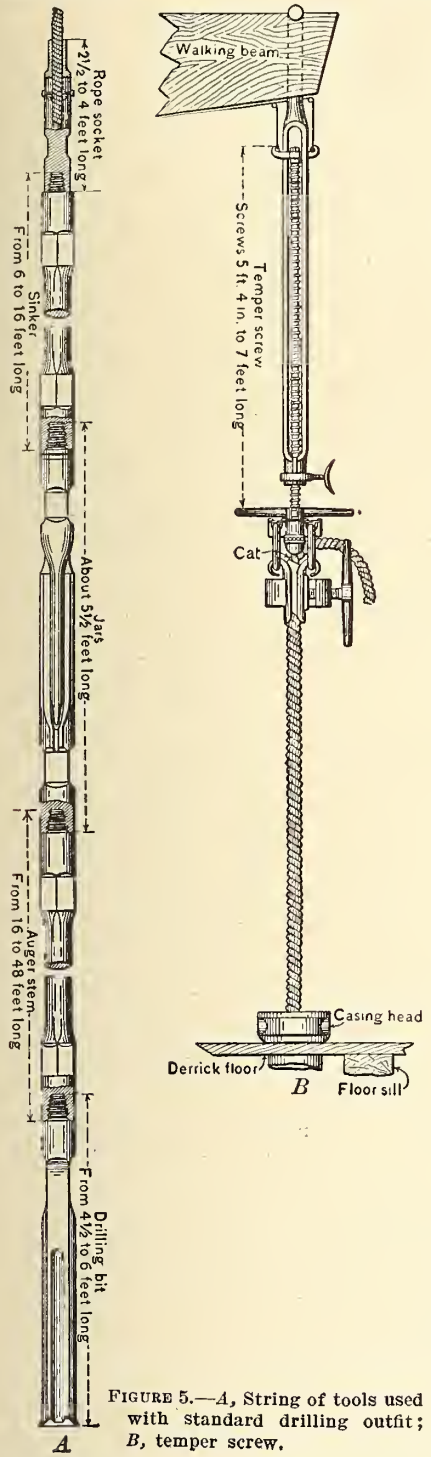


FIGURE 5.—*A*, String of tools used with standard drilling outfit; *B*, temper screw.

n the vicinity of Bradford, Pa., water is obtained fr m wells about 60 feet deep in the valleys and 200 to 300 feet deep in the hills. The cost of sinking water wells adds considerably to the expense of putting down o wells.

Tools.

The string of tools used in deep drilling consists of several parts, all of which have certain definite functions and are the outgrowth of years of experience. A full string (fig. 5, A) comprises rope socket, sinker bar, jars, auger stem, and bit. Whether or not the complete string is used depends on the conditions under which drilling is done.

The socket may be fastened to the drilling rope in several ways. It may have a tapered hole in which the rope is secured by knotting; the rope and socket may be riveted together, or the rope may be threaded back and forth through several holes in the socket and secured by wedging.

The sinker bar is a long, heavy bar, which is used to add weight and length and thus aids in keeping the hole straight. It was formerly thought to be an essential part of the string, but it is now seldom used unless a wet hole (one partly filled with water) is being drilled. It then assists in sinking the cable rapidly. If it is placed between the jars and the bit, it adds force to the blows of the latter.

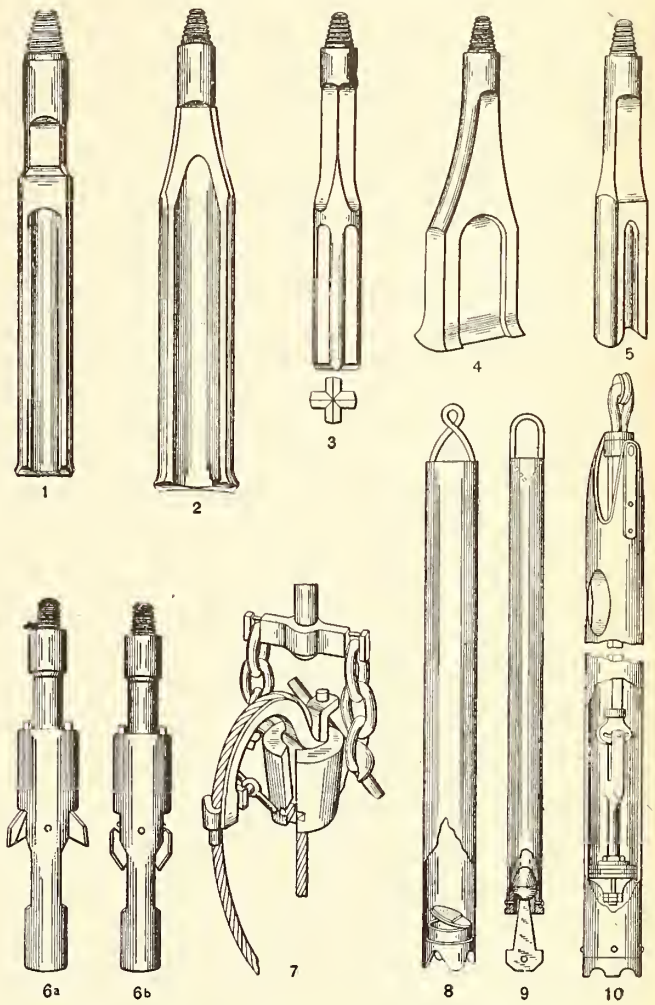

Figure 6. Drilling tools used with standard drilling outfit. 1-5, Bits; 6a, 6b, reamers; 7, rope clamp; 8-9, sand bailers; 10, sand pump.

The jars, as previously stated, consist of a pair of linked steel bars. When drilling in rocks in which the bit is apt to stick they are necessary to "jar" the drill loose. The drill responds to the powerful upward blow of the jars as they are jerked violently together by the stroke of the walking beam when it will not yield to the slow and relatively steady pull of the rope. In ordinary brittle rock the jars are now almost universally discarded, but they have a very important use in "fishing" for lost tools; those intended for this purpose are made longer than jars used in ordinary drilling.

The jars in no sense act as a maul to drive the drill into the rock, as many people suppose. In fact, a good driller so adjusts the cable that it is impossible for the upper jar to strike the lower one except when the cable is raised. The only weight which adds effectiveness to the blow of the drill is the weight of the lower jar, the auger stem, and the drill. The weight of these three parts, or of the two last-named parts, makes up three-fourths to seven-eighths of the total weight of the string of tools. This weight, falling through a distance of several feet, is all that the drill can bear. Some inexperienced drill men give the drill too much rope, so that the bottom of the upper jar strikes into the bottom of the slot of the lower jar at each downward stroke, and in a short time the links are seriously damaged. The stroke must be carefully adjusted to the play of the jars, taking into account the stretching of the rope.

The auger stem gives additional weight to the blows that are struck, and also, by increasing the length of the drill, helps to maintain a straight hole. It is of the same shape as the sinker bar, but is considerably shorter.

Various patterns of drilling bit are used, according to the character of the rock that is being penetrated. The shape illustrated at the bottom of the string of tools in figure 5, A, is used in moderately hard rock; the "Mother Hubbard" pattern (fig. 6^1) is a similar, but thicker, drill that is used in hard, fissured rock; the California pattern (fig. 6^2), which is concave on the bottom, is much used in the shales of the oil districts in that State. A shorter, lighter bit (fig. 6^3) is used in "spudding" at the beginning of drilling. Star bits (fig. 6^4) are sometimes used in crevieed rock that dips steeply, and more complex shapes are used in reaming and in other special operations.

All joints of the string of tools have taper screws, so that only a few turns are required to fasten them together. They are screwed up tightly by heavy wrenches on which great leverage is exerted by means of a ratchet floor circle and jack (fig. 7, A), or by a simpler arrangement (fig. 7, B) in which the floor circle is an arc of band iron with holes punched in it every 2 or 3 inches. These holes give footing to a bar by which the upper wrench is forced around. The great stress that is thus brought on the screw joints binds the string of tools together. When first assembled and screwed together tightly each joint of the string may be marked by a cold chisel cut that extends across it, and each time a joint is put together care is taken to see that it is screwed up as far as or a little farther than it was before If the two halves of the chisel mark fall short of coinciding, sand or mud in the threads may be the cause, and if this material is not removed and the joint screwed together tightly, the sand may work out, leave the joint loose, and cause loss of all tools below the joint.

Temper Screw.

The cable supporting the string of tools is connected to the walking beam by a temper screw (fig. 5, B), which allows the drill to be fed downward as the drill hole is deepened. The temper screw consists of a frame or reins, at whose lower end is a split nut held together by a yoke clamp. Through this nut the main screw passes, and to its lower end is fastened a handle, by which it is turned. Below the handle is attached a ball-bearing swivel, from which depend the rope clamps by a C clamp and is prevented from slipping by means of a "cat," made of strands of ravelled rope or strips of coarse cloth, loosely plaited or twisted so as to form a cord about as thick as a man's finger in the middle, and tapering toward each end. The "cat" is wound about the cable at the point where the clamps are attached, and the set screw is then turned so as to bring the rope clamps firmly against it. Slightly different forms of clamp (fig. 6^7) are sometimes used with wire rope.

When the screw has been run out its full length, and it is desired to bring it up again, the slack of the drilling rope is taken up on the bull-wheel shaft, the pitman of the walking beam is disconnected, and the C clamp is loosened. The yoke clamp is then loosened, the main screw is drawn up through the split nut, the yoke clamp is again tightened, and the temper screw

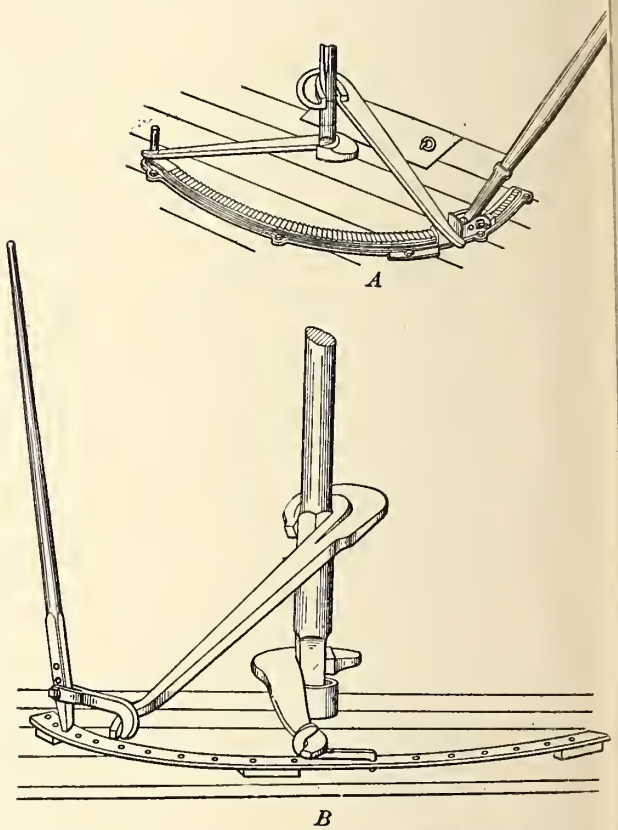

Figure 7. Floor circles; A, Rachet and jack; B., bar and perforated arc.

clamped to the cable. Small ropes are fastened to a short crossbar, or elevator, at the upper end of the main screw, and by pulleys on the under side of the walking beam a counterweight is hung beside the samson post. This weight balances the temper screw and renders its raising easy.

Cable.

Both hemp and steel-wire ropes are now used for drilling cables, the steel wire having come into more general use during the last ten or fifteen years.

The best quality of hemp rope is that made of manila hemp (not common hemp nor sisal) and is hawser laid, that is, it consists of three ropes of three strands each, twisted together into a single rope. In its manufacture a "nap" is formed, of the ends of hemp fibres, nearly all of which point toward one end of the rope. The rope socket should be fastened to the end toward which the fibres point, for although when the tools are attached to this end the fibres spread out and retain

e downward stroke in a hole that is partly filled th water, they protect the rope better from being yed by rubbing against the casing on the upstroke.

Steel-wire drilling cable is composed of several sands wound about a hemp centre, each strand being fmed of several wires. Rope consisting of six strands o seven wires each is a style commonly used.

The advisability of substituting steel-wire cable for hmp cable in drilling deep wells has been much dissed, some maintaining that hemp can never be reced by steel, and others that steel will shortly be ed altogether. The importance of the substitution o steel for hemp is better appreciated when it is known t at a hemp cable ordinarily can not be used to drill re than one or two wells, but the hemp cable possses certain important qualities which are not found i the steel cables and which must be considered in caling with the problem. The careful driller never aows his tools to fall as a dead weight on the rock vich he is drilling, but so adjusts the rope that the tols will stretch it in reaching the bottom of the hole. Te nature of this action may be illustrated by susnding a weight by a piece of rubber elastic a little aove a table or other surface. It will be found that b giving a slight reciprocal motion to the rubber the veight may be made to strike the surface with conserable force. Manifestly, the force of the blow is dminished by this arrangement, but in drilling this ls of force is more than compensated by the springig blow that is struck; and if the rock is easily cut b the drill this rebound is essential, as otherwise the dill will be imbedded so firmly as to make it difficult t remove except by jarring.

In drilling a deep well the stretch of the rope is often uderestimated, and it may happen that the tools are fling when the walking beam is rising, thus bringig a great strain on the cable and making the blows o the drill very ineffective. The operation of the tols is rendered still more difficult when the hole contns several hundred feet of water, which interferes vth the free upward and downward motion of the cole.

Steel cable, with its smaller diameter and greater veight, has the advantage of passing comparatively feely through water which may stand in the drill hle, the water friction being much less than on a hmp cable, and the water also reduces the shock of te steel cable by acting as a deterrent to the rapid cop of the tools. On the other hand, steel cable has vry little elasticity, and drilling by the stretch of the rpe is hardly possible. Every blow that is struck b the drill is a dead blow, as there is no compensating rbound and the upward stroke causes severe strain, lth on the derrick and on the cable itself where it is atached to the tools at its lower end and to the temr screw at its upper end. The difference in stretch c the two kinds of cable is shown by the fact that vth a 5-foot temper screw 7 or 8 feet may be drilled vth hemp cable, while at best a distance of only 5½ fet is possible with steel cable. Some drillers use 150 c 200 feet of hemp rope between the tools and the seel rope, and this gives some elasticity to the cable ad rebound to the tools.

The use of the steel cable was considerably increased dring the Spanish-American war by the fact that the pice of hemp cable became so high that its use seridsly increased the cost of a well.

In the last few years at least half of the oil wells pt down in the California fields, where the wells are ually drilled "wet," have been drilled with steel cables. In other oil fields a very small proportion of the drilling is done with steel cables. For cleaning wells, however, it has largely supplanted hemp cable throughout the east, as in this work it is not necessary to use such a rapid strike, and hence steel cable may be advantageously employed.

The standard well-drilling outfit with steel-wire drilling cable has been used to some extent in the Baku oil region of Russia, where it was found that only a very limited amount of rotation could be imparted to a wire rope without damaging it, because of the untwisting and kinking of the strands. To overcome this disadvantage a special kind of wire rope was employed, consisting of left-hand and right-hand strands plaited together. It is said that this rope worked satisfactorily in the hands of a skilful attendant, but it had to be disconnected from the main drum at each change of operations.

Drilling Operations—Spudding.

The term "spudding" is often misunderstood. By some people it has been thought to mean the preliminary part of drilling, without reference to the way in which the drilling is conducted; by others it has been interpreted to mean drilling in rock of unusual hardness. Properly, however, the term is applied to drilling without the aid of the walking beam — the method nearly always used in sinking the first 75 or 100 feet of a well, as the string of tools is too long to be operated from the walking beam in beginning work. It is possible to attach the tools to the drilling cable before the hole has been drilled to this depth, but owing to the short length of cable between the tools and the walking beam there is very little "spring" in the rope, and the hole must be spudded to a sufficient depth to allow a considerable length of cable to come between; otherwise the blow of the drill will be "dead" and the rope will be likely to break.

For spudding a short cable is run through the crown pulley at the top of the derrick, one end being attached to the bull-wheel shaft and the other to the rope socket, to which are usually screwed only the auger stem and spudding drill. The drill may be given an up-and-down motion in two ways: In the first method the rope is carried around the bull-wheel shaft in two or three turns, its end being left free. A man standing in front of the bull wheels grasps this free end of the rope and gives a slight pull, causing the coils to tighten and grip the revolving shaft, and by this means raising the tools; when the rope is slackened the tools fall. By alternately tightening and slacking the rope the operator may raise and drop the drill. The second method has come into use comparatively recently and is much more effective than the other. In this method, which is self-adjusting, the drill rope is wound firmly about the bull-wheel shaft and passed through the crown pulley, and from its end the tools are suspended in the drill hole. A rope called the jerk line is attached to the wrist pin of the band-wheel crank, brought inside the derrick, and attached to the part of the drilling cable which extends from the crown pulley to the bull-wheel shaft by a curved metal slide called a spudding shoe. (See fig. 8). By carefully adjusting the length of this rope each revolution of the band wheel results in a pull on the line and its subsequent release, and a corresponding rise and fall of the tools. As the hole is deepened the cable is let out by giving the bull-wheel shaft a partial revolution, and the spudding shoe is slipped farther and farther down,

for this downward sliding of the spudding shoe increases the length of the pull on the drilling cable and hence the distance through which the drill drops. The sliding motion is imparted by the driller's assistant, between the jerks of the line, by means of a crooked stick long enough to reach the spudding shoe from the floor of the derrick.

Spudding is much harder on the derrick than is ordinary drilling, as the strain is brought on the top of the derrick where there is the greatest leverage. In drilling with the walking beam the weight comes on the samson post, which is not directly connected with the derrick, and the strain comes on the derrick only when raising or lowering tools or casing and when using the sand bucket or the bailer.

Drilling with the Walking Beam.

After the hole has been sunk to the depth required for the string of tools a heavier drilling bit is attached, the drill rope is suspended from the walking beam by the temper screw, and regular drilling by means of the walking beam is begun. To allow freedom of motion to the walking beam, 20 or 30 feet of the drill rope are unwound from the bull-wheel shaft and loosely coiled on the floor. The pitman of the walking beam is then

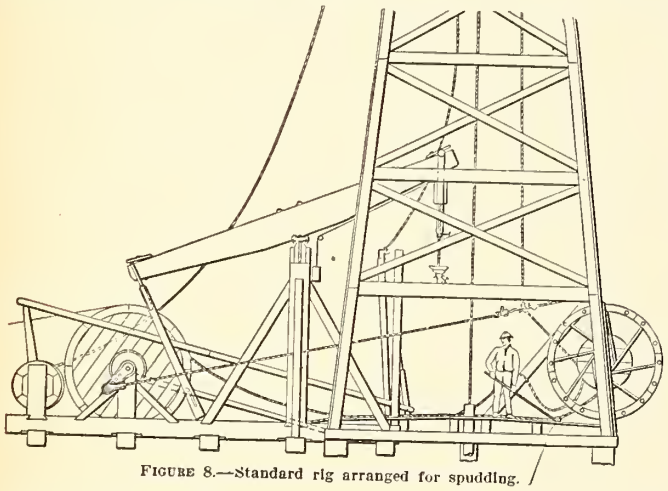

FIGURE 8.—Standard rig arranged for spudding.

fastened to the wrist of the band-wheel crank. The crank is provided with a number of holes, so that the length of strike can be adjusted to the depth of the well, a short stroke being used near the surface, as the strain would otherwise be too great for the rope to bear. The engine is then started and the walking beam begins rocking up and down, raising and dropping the tools at the rate of about 25 strokes a minute.

Until within the last few years it was the custom to revolve the drill by inserting a stick in the rings below the temper screw and slowly turning the rope first in one direction and then in the other. This was thought to insure a round hole by causing the drill to strike each time in a different place. One day a tired workman, who wondered if this operation was necessary, neglected this precaution and found that the drill still made a round hole, a fact that had often been inferred by drillers who had seen the tools revolve and bring the drill in a new position for each stroke. The drill is jerked free from the rock unevenly, and the torsion of the drilling cable under the lifting strain has the effect of rotating the tools in one direction on the upstroke and in the other on the downstroke. This action, however, takes place to a notable degree only when there is a sufficient length of rope between the tools and the walking beam; until a considerable depth is reached it is often necessary to turn the cable by hand, otherwise the drill may strike successive blows in the same place, but it is now rightly considered that after the hole is 200 or 300 feet deep it is needless to turn the rope while drilling.

The skilled workman takes hold of the rope or swivel often, for by the feel of the rope he ascertains whether the string of tools is intact and the drill is cutting the rock. When the drilling bit strikes the bottom of the well, the cable is drawn taut and conveys the vibration to the driller's hand; by this means he soon learns when to adjust the temper screw. In the same way the operator learns whether or not the jars open and shut at each blow of the drill.

The proper tension of the cable can be determined only by practice. An old cable has more spring to it than a new one; and the weight of the drilling tools, the depth of the hole, and the speed at which the machine is running must also be taken into consideration. Ordinarily the engine should be speeded up until the cable tightens slightly in advance of the stroke of the drill, not so as to retard its fall, but so that when the drill touches bottom it will be instantly lifted, with no time either to settle or stick. This careful adjustment of the stroke is absolutely necessary for rapid and skilful work. If the drill touches bottom when at rest there is too much rope out and it should be taken up with the temper screw, for the downward stroke of the drill will stretch the rope sufficiently to let the bit strike the bottom of the hole.

The motion of the drill will be greater than that described by the walking beam, unless too much cable is let out, in which event the stroke of the drill will be less than the stroke of the walking beam, the strain on the cable will be greatly increased, and little or no progress can be made. One of the hardest things for a beginner to learn is that he can not make the drill cut faster by letting out more cable. With a heavy cable, at a depth of about 50 feet, when the drilling tools are at the lowest point in the stroke, the point of the bit should hang 2 or 3 inches above the bottom of the hole. At 100 feet it should be 4 or 5 inches; at 200 feet it should be 6 to 12 inches; and at greater distances with greater depths. An unskilled driller will sometimes allow the full weight of the tools to fall on the drill rope, the drill actually being stopped in its descent a short distance above the rock in which it is supposed to be cutting. The likelihood of such an occurrence increases with the depth of the hole, for the increasing weight of the drill rope, added to the weight of tools, often several tons in all, makes it difficult to detect by the "feel of the rope" whether or not the total weight is decreased at the end of the stroke by the weight of the tools below the jars.

As the drill cuts deeper it is necessary to let out the drill rope gradually, so that the drill will strike bottom at each stroke. This is done by loosening the yoke clamp a little, and running out the temper screw a turn or two. At the end of from half an hour to several hours the temper screw has been run out its length of several feet and the drill has advanced an equal or greater distance. The tools are then withdrawn, the waste that has accumulated since the last bailing is removed with the sand bucket, and, if necessary, a sharpened bit is substituted.

The withdrawal of the tools is accomplished by first taking up the slack cable on the bull-wheel shaft, thus transferring the weight of the tools to it through the crown pulley. The rope clamp is then loosened, the temper screw is disconnected, and the pitman is thrown

rom the band-wheel crank pin, as in figure 8. By ting the bull-wheel shaft with the engine connec- the tools may then be raised or lowered at will. h part of the work demands skill, for if the bull- wh el brake should not be applied as the tools reach the surface, the crown block and pulley would be torn loo and the tools would fall on the workmen beneath. Af r the tools are clear of the hole, they are swung to ne side and caught in the loop of a quarter-inch ro fastened to a leg of the derrick.

he operator is now ready to bucket the drillings fro the well. The sand bucket, or bailer, consists of a s ction of tubing 15 to 60 feet long and somewhat sm ler than the well. It has an iron valve at the bot- tor either of the flat pattern, or the ball and tongue pa ern. (See fig. [8 9].) In some materials in which the dr ings are thick and heavy and do not readily enter the bailer, a sand pump (fig. 6[10]) is used. In addition o e bottom valve this has a plunger which is worked lik that of a water pump, and thus sucks the drillings in t the tubing. The bucket or pump is suspended fro a wire cable that is wound on the sand-line reel an carried through the sand-line pulley. The reel is ope ated from the derrick by a lever, which brings its fri ion pulley into contact with the band wheel. The san -bucket line is thus wound up and the sand bucket is s ung over the hole. The friction bearing on the ear wheel is then released and the bucket is lowered int the well at any desired speed. As the drillings 'or a thin mud, owing to the addition of water from tim to time by the driller, they rise into the sand buc et, are retained by the valve in its bottom, and are hen removed. The bucket is emptied by lowering it on an upright stake or pin beside the well, thus ope ing the valve.

The liquid condition of the drillings often makes it pos ble to drill 5 or 6 feet without bucketing; other- vis the drill would become ineffective at the end of a v y short time, by striking into its own cuttings, and the ecessity for frequent bailings would greatly in- rea e the work and cost of drilling. Water is usually add to the drillings by the bucketful at the well nea Sometimes it comes into the well from water- ea ng strata that have been penetrated by the drill in a quantity sufficient to soften up the drillings, and yet ot great enough to interfere with the work.

I many localities water is added to the drillings by ea s of a barrel set at one side of the derrick, from the ower end of which a pipe extends within 2 or 3 feet of the drill hole; to this pipe is fastened, by a loos joint, another piece of pipe as long, at least, as the eight of the barrel and long enough also to reach fro the end of the horizontal pipe to the mouth of the rill hole. When the short length is dropped to a hor ontal position water flows from the barrel down into the hole; by raising the short pipe to a vertical pos ion the flow is shut off.

Dressing the Bit.

A the bit gradually becomes worn on the edges, its dia eter is constantly reduced — that is, it loses its gau e. When the tools are withdrawn, if the bit has bec ne noticeably worn, the screw joint connecting the it and auger stem is "broken" by means of the wre ches and floor circle, the bit is unscrewed and re- mov d by hand, and a freshly dressed bit is then sub- stit ed. During the first part of this operation the tool are steadied by keeping them partly in the drill hole At this time the whole string of tools is usually examined, and each joint is "set up" in turn, as the constant and tremendous jarring to which the tools are subjected tends to loosen the different parts. Before drilling is resumed the temper screw is also screwed up or "elevated" so that it can be fed down as the drill hole deepens. The tools are then let down again and drilling is resumed.

The worn bit is heated in the forge, the circular tool gauge is slipped over while it is hot, and the edges of the drill are hammered out to fit the gauge, which has a diameter one-eighth inch greater than the required diameter of the bit, to allow for contraction due to cooling. In heating the bit it should be turned occasionally to get an even heat, and brought to a cherry red for a distance 3 or 4 inches back from the end, so that in hammering it the outer part will not tend to spall off. It is usually spread with a sledge, working from the centre to the edges, to a diameter a little larger than the gauge, and then hammered down to proper size. The edge should not be made very sharp or it will tend to drill a three-cornered hole. In tempering the end is heated until it shows bright cherry red in the shade, then placed upright in 1½ or 2 inches of water so as to cool only the part to be tempered. After a minute or two, when the edge is cool, the bit is removed until the heat flows back into the end and causes it to pass through straw, orange, and purple to a blue colour. It is then re-immersed and allowed to cool. The treatment gives the proper temper for drilling moderately hard rock. If the bit is cooled at one of the colours that appear earlier, it will be too hard and brittle to work well, and if allowed to wait longer before tempering it will be too soft. The upper (threaded) end of the drill should be thoroughly cooled before it is screwed to the stem otherwise subsequent shrinkage may cause the joint to loosen.

As the bit becomes worn by continued drilling, the size of the hole is correspondingly decreased. In hard sandstone one-quarter to three-eighths of an inch may be worn from the width of the bit in drilling 3 or 4 feet, so that when a newly dressed bit is introduced it may find the last few feet too small, and may work hard or even stick for the first few strokes. A well-worn bit will cut a hole no larger than its shank, but a newly dressed bit provides clearance, like the teeth of a newly set saw. To prevent sticking the bit is run up and down a few times and turned constantly. It is thus prevented from forming a groove which it would tend to follow so as to direct the repeated strokes of the drill in the same place. When the rock is very hard and the bit is more rapidly worn, jars are necessary to prevent accident to the drill rope by the sticking of the drill.

Wet and Dry Drilling.

A "wet" hole is one in which water in excess of that required for the operations is present while drilling; a "dry" hole is one in which excess water is cased off during the sinking of the well. In oil fields these terms are applied in a different sense, a wet hole being a well which yields oil and a dry hole one which does not.

In a dry hole the drilling can be done faster, as the tools are not buoyed up by water; the rope lasts longer because it is not always saturated; small showings of gas and oil are more readily detected and their depths are more accurately determined; and if the tools are lost in the hole, they can be more easily recovered, as fishing tools are used to better advantage

in a dry than in a wet hole. At Bartlesville, Okla., three water-bearing sands are encountered in drilling for oil. Dry drilling in that field is regarded as so much more satisfactory than wet drilling that three strings of casing are inserted to keep the water out. Two of these are withdrawn when the well is completed, the last one that is inserted being kept in service to retain the oil and prevent the well from caving.

Wet drilling is usually cheaper (there being no outlay for additional casing), no time is lost in putting in casing and replacing the tools by a smaller set; and when the well is down, the charge of nitroglycerine used in shooting the well has much greater effect, as it is tamped by the heavy column of water. The greatest disadvantage of wet drilling is that the sides of the hole are kept so wet that some of the shales are reduced to a semi-fluid mud, which frequently caves. Another disadvantage is that when tools are lost there is danger of sand and mud settling around them, even if the sides of the well do not cave.

Casing the Well—Conductor Box.

In many places the surface material consists of loose sandy clay, sand, and gravel, varying in thickness (in the Pennsylvania oil regions) from a few feet on the hills to several hundred feet in the valleys. To restrain this material, which would otherwise impede the work of drilling, a conductor box, made of plank, circular, square, or octagonal in shape, and 8 inches to 20 inches across, is sunk to the bed rock. If the rock lies only a few feet below the surface the necessary excavating is done by hand; if the soil is deep, a large drilling bit is used to spud down a hole, into which the conductor box or a section of large iron pipe may be sunk as fast as drilling proceeds.

Casing and Drive Pipe.

After passing through the surface material the drill enters the "live" rock. As a rule this rock is made up of alternating layers of hard and soft, of very porous and slightly porous, of water-bearing and non-water-bearing rock that is encountered after passing through the water-bearing layer. This casing is set very firmly into the hard layer and shuts out the water. In order to continue drilling it is necessary to use a smaller bit which will pass, with clearance, inside the casing. If other heavy flows of water are encountered at greater depths, each flow must be cased off by a string of casing extending from the surface to the bottom of the water-bearing layer. As each string must slip inside the preceding one, a smaller drill must consequently be used after each casing operation.

The first well lining used in this country was in the celebrated well drilled by Colonel Drake on Oil Creek, Pennsylvania. Some of the early drilled wells of small diameter were lined with pipe made of rivetted or soldered sheets of copper. Before long this was superseded by drive pipe with soldered brass screw joints, such as is still used in the salt wells of Tarentum, Pa.

Several varieties of casing are now used. Sheet-iron rivetted pipe is extensively employed in the Russian oil fields, but it is little used in oil wells in the United States. It is rather short lived, and the corners of the bit are apt to catch on it in drilling and cause breaks. Another kind of pipe used, known as oil-well casing, ranges in usual sizes from 4 to 12 inches, inside diameter, and is made in several weights. A third kind, called steam pipe, is also made in sizes up to 12 inches and in three grades—standard, extra strong, and double extra strong. Still another kind of lining is the regular drive pipe, which is made very heavy in order that it may be driven to great depths. The ends of the pipe are cut off smoothly and squarely in the middle of the sleeve coupling (fig. 1). In this way the whole strain in driving comes not on the threads, but on the pipe; otherwise the joints would be disabled before reaching any considerable depth.

If a cheap well is desired, heavy wrought-iron

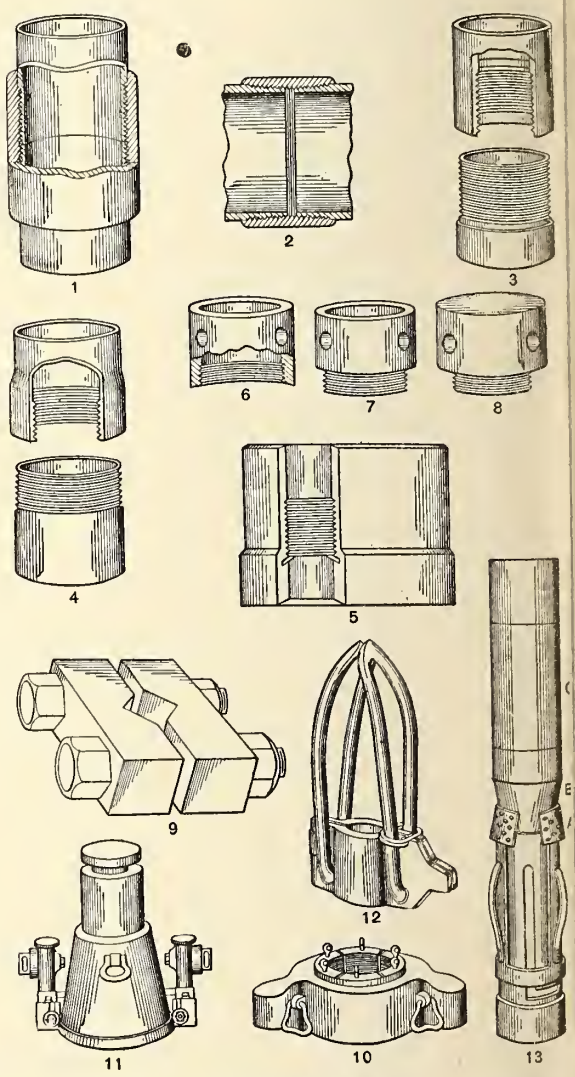

Figure 9. Couplings and casing attachments. 1, Sleeve coupling; 2, Tapered sleeve coupling; 3-4 Sleeve and inserted joint couplings; 5, Shoe; 6-7-8, Drive heads; 9, Drive clamps; 10 Pipe ring; 11 Hydraulic jack; 12, Elevator; 13, Gas packer.

is driven to rock, and the well is finished by drilling to the required depth. A casing made of sheet iron, one-sixteenth inch thick and one-half inch smaller than the drilled hole, is then used. If it is necessary to shut off sand the bottom of this pipe may be flanged outward a little. After the sheet-iron pipe has been placed in the well the heavy pipe may be pulled out and used again. If the depth to rock is not more than 50 or 75 feet and the material is all clay or earth which will not cave, the heavy pipe may not be used at all, the sheet-iron pipe serving in its stead, though its use in this way is attended by considerable risk

sing is usually a lighter and cheaper pipe than pipe, as it has little outside pressure to with-. A tapered sleeve coupling (fig. 9[2]) is often with it. In this form of coupling the last thread tube is the weakest and most likely to break in f accident, and the pipe is easier removed than if hole thread remained in the tube. Flush joint nserted joint couplings (fig. 9 [3 4]) are also used casing that requires little driving. After a few well have been sunk in a district the approximate nt of casing that will be required for a well can ly be estimated, since the depth to troublesome -bearing formations is then roughly known.

In gas wells, where dryness is essential, all the gs of casing are usually left in the well to prevent near the surface from sinking to the lower end the last casing, where it would be under great head night force its way through a weak spot at the of juncture of the casing with the rock. As a foot of water weighs about 62½ pounds, the ure, in pounds per square inch, of the column of in the drill hole is equal to the height of the n in feet, multiplied by 0.434. Therefore at the m of a well 1,500 feet deep water that enters and t up to the 500-foot level exerts a pressure of 434 ds per square inch. This is the crushing stress on ipe provided there is no internal column of liquid unterbalance the external column, as, of course, is not in a producing gas well.

In deep drilling, where caving material may be en-ered, it is customary to sink casing, or drive as fast as drilling proceeds. For this purpose heavier than the usual casing is employed, and ger joints are made generally by heavy sleeve ings (fig. 9[1]). On the bottom of the lower joint is screwed or shrunk a shoe of tempered steel 9[5]), which will stand heavy driving without in- and which gives clearance for the pipe and ings. The ordinary pipe would be greatly dam-in driving long distances if it were not protected is shoe. To prevent the top of the pipe from be-battered, a drive head (fig. 9[6 7]) is screwed or d on it. In some places the material is so loose the tubing will follow the drill for some distance ut requiring to be driven: but when driving be-s necessary drive clamps (fig. 9[9]) are bolted to in square of the upper end of the auger stem. The inery is then coupled as for spudding, and 50 or ows a minute are delivered by this driving clamp drive cap on the top of the pipe. The pipe may e driven by a heavy wooden maul attached to the rope. In this case a solid drive head (fig. 9[8]) is and proper direction and effectiveness are in- to the blows by means of temporary guides set n the derrick.

Sometimes in drilling through a compact foundation, as clay, the pipe becomes lodged, owing to the ction of the couplings. When this happens a cap ewed to the drive pipe, and water is forced down as to come up outside of the pipe and loosen the rial about the coupling.

When the pipe has been driven as far as practicable ng is resumed. The driller endeavours to keep the sunk a few feet ahead of the casing, for in this way the casing is let down straight, whereas if the is driven ahead of the drill, it may be deflected its course by changes in the hardness of the ma- or by encountering a boulder or a layer of coarse el.

This method, however, can only be used where the material will stand up for some distance without the support of the pipe. Quicksand will flow around the bit and even rise in the pipe, and in this material the pipe must be driven down to the bottom of the hole and kept ahead of the drill. If the bed of quicksand is not thick, the difficulty of drilling through it will be slight, but where beds 50 or 60 feet in thickness are encountered, some of the greatest difficulties known to well engineers have to be met and overcome.

When long and difficult strings of casing or drive pipe are to be withdrawn or "pulled" from a well, as on completing or abandoning it, a pipe ring (fig. 9[10]) is placed over the upper end of the pipe; this ring grips the casing firmly by means of its corrugated iron wedges and is then subjected to upward pressure by specially designed hydraulic lifting jacks. (Fig. 9[11].) When short or easily pulled lengths are to be removed, wrought-iron elevators (fig. 9[12]) are clamped to the upper end of the last length of pipe, are caught by a hook suspended from the derrick, and are tugged upward by means of pulley sheaves.

Several machines for pulling casing are on the market. For pulling casing from abandoned wells they have the great advantage of portability, and they are cheaper and more efficient than a derrick erected over the well.

CONSOLIDATED M. & S. CO.'S RECEIPTS.

The following figures show the tonnage of ore received at the smeltery at Trail, British Columbia, of the Consolidated Mining & Smelting Company of Canada, Limited, during the expired nine months of the company's fiscal year to April 1; also the quantity of ore smelted each month, the approximate gross value of the metals contained in the same, and the percentage of gold included:

Month.	Tons.	Tons	Approximate	Percentage
1910—	Received.	Smelted.	Gross Value.	of Gold.
July	35,641	35,138	$384,000	62.7
August	33,453	32,301	420,000	49.5
September	33,333	31,105	288,000	57.5
October	34,356	34,132	430,000	47.2
November	35,053	36,066	421,000	56.5
December	35,310	36,364	351,000	53.4
1911—				
January	34,505	32,958	349,000	57.7
February	32,323	32,315	328,000	57.8
March	35,096	34,208	365,000	54.8
Totals	309,070	304,587	$3,334,000	55.2

Of the total quantity of ore received, as above, 46,755 tons was custom ore and the remaining 262,315 tons came from the company's own mines, as under:

	Tons.
Centre Star group, Rossland	139,972
Snowshoe, Boundary	83,201
Sullivan, East Kootenay	25,362
St. Eugene, East Kootenay (concentrate)	6,129
Richmond-Eureka, Slocan	2,476
Queen Victoria, Nelson	1,984
No. 7, Boundary	1,718
Phoenix Amalgamated, Boundary	1,143
Molly Gibson, Nelson	330
Total output for nine months	262,315

The greater part of the ore from the company's mines was gold-copper, namely, 228,018 tons; the remaining 34,297 was lead-silver ore and concentrate.

SPARKS AND BRAKES

Safety in Mines.

(Reprinted from the Engineering Supplement of The Weekly Times, London.)

Among the various causes that are assigned to recent explosions in mines it is usual to include as a possibility the ignition of inflammable gases by sparks arising from mechanical friction in belts or gearing associated with the haulage plant or with the brakes used for controlling the speed of haulage. It is also suggested that with the modern tendency to speeding up the machinery used in mines this risk of ignition is increasing. The question is one for investigation rather than for dogmatic expression of opinion, and it is desirable that the evidence so far available should be examined, and that the matter should be made the subject of organized experiment.

Since Bochet in 1861 published his remarkable treatise regarding his "Recherches Experimentales sur la Frottement de Glissement" the theory of sliding friction has advanced but little. Rochet showed how tests should be made, and he indicated how results could be usefully compared by deducing certain coefficients of friction from the observations. Moreover, he determined the coefficients for various woods, leather, gutta percha, and metals, investigated the effect of moisture upon the rubbing surfaces, and generally laid the foundations of present knowledge of the subject. In the meantime a vast amount of information has accumulated regarding the energy frittered away as heat arising from friction and in regard to mechanical devices for reducing frictional losses; but we have learned very little in respect to the formation of sparks generated mechanically by abrasion. The flint and steel and its precursors have grown up with the human race, with the result that sparks are naturally regarded as fire originators. The power of the spark to cause ignition is, however, a question of degree, and what is now required is an investigation of the circumstances in which it becomes potent in causing explosions.

There is general agreement that sparks from brakes are the result of friction, but the term "friction" is often used vaguely, as though it were a constant quantity for two given surfaces, such as those between a given brake-block and a given wheel-rim. Friction is measured by the proportion which the sliding force—tending to cause relative movement between the two surfaces—bears to the pressure between those surfaces. If the sliding force and the pressure are adjusted so that the surfaces are about to move relatively upon one another, without actually moving, the proportion between them, or the "static friction," is greater than when the forces are adjusted to permit of decided movement, which corresponds with "kinetic friction." Friction, therefore, varies with the speed, and for a given pressure it is greatest at low speeds. It is usual to assume that it depends upon the total pressure, and that for most purposes it can be assumed to be independent of the area of contact. Where the heat problem is concerned, however, the question of area of contact would certainly require to be taken into account. In order to slow down a piece of mechanism the brake must rob the moving masses of energy; and with our present crude methods of retarding moving masses the whole of this stolen energy must appear as heat at the brake surfaces. materials used for brake-blocks must therefore be s as to get rid of the heat as quickly as possible, they must be able to withstand high temperatu Again, it has to be remembered that with band-br devices the friction may differ considerably at dif ent points throughout the length of the band, ow to different radial pressures, and that heating consequently be of a local character.

Temperature and Ignition.

The process of abrasion may be pictured as a se impacts distributed over the surfaces in frictional tact, and succeeding one another with a degree rapidity depending upon the rate at which the bing surfaces move with reference to one another. any selected small area of the surface, these imp —which are for the most part tangential—may be garded as a succession of glancing blows struck b hammer upon an anvil. The energy of the blow is solved into (1) the energy required to shear off abraded material; (2) the energy that heats the h mer and the anvil; and (3) the energy that heats abraded particles. It is thus seen that the initial t perature of the particles is due to the hammer and vil process. The subsequent temperature of the ticle may arise from rapid oxidation at its new faces, assisted by the initial heating. Thus it probable that the temperature of the particle at spark stage depends upon the magnitude of the pact, the specific heat, the thermal conductivity, tenacity constants and the coefficients of friction the substances in contact, and the nature of the rounding air or gas. These temperatures, in the of such a material as iron, might be roughly estima in certain cases from the colour and brightness of sparks. It has been stated that the temperature ignition of coal dust is 180 deg. C.; and one obser who heated coal dust in an air bath succeeded in niting it at 140 deg. C. Consequently, as the t which nevertheless ignite those gases because of extremely high temperature of their flames. Agai spark is certainly not a detonator, and the investi tion would have to be extended to examine the perature of a spark struck off an iron wheel may ture of the ignition, if any, that it produces in resp anything up to about 1,000 deg. C., there is a c prima facie case against sparks—provided that t perature at a single point and apart altogether fr considerations of time and heat capacity is al taken into account.

It is well known, however, that the temperature ignition in the case of explosive mixtures is a comp function of the time and possibly of the volume. exploding process is chemical as well as physical, the initiation and propagation of the chemical act is not necessarily instantaneous. This principle is basis of the theory of the so-called "safety" exp sives for shot-firing in mines. In the ignition of g powder, for example, the flame and the gases rounding the flame are held for a comparatively l time in contact, with consequent great danger of

sion of mine gases; and for this reason the use of powder for blasting purposes in mines has had to be abandoned. It must be remembered, however, that at the other end of the scale there are explosives which, when detonated, provide very short contact between their flame and the surrounding gases, and to the rate of combustion of the gases in the immediate vicinity.

Absence of Positive Evidence.

In the more recent Home Office reports upon mining disasters resulting from explosions and fire there seems little positive evidence to support the spark theory of ignition. The Hamstead Colliery fire, which occurred in March, 1908, happened while the winding engine had broken down, leaving 250 men below ground, who had to be drawn up slowly. In the words of the report, "the pit was laid off actual coal-producing work, and was in this condition at the time of the accident." As, in addition, the evidence is definite that lighted candles were used in the mine, it is entirely unnecessary to consider the effect of mechanical friction in this instance.

In the case of the explosion in the workings of the West Stanley Colliery in February, 1909, the evidence was so conflicting that it was difficult to arrive at any conclusion regarding the cause. The official report is to the effect that at first it seemed as though the place of origin was in or about the hauling engine-house, and that to some investigators it appeared possible that it might have occurred in the engine-house itself. Finally it was considered more probable that it originated at a point in the workings where there was a heavy fall, burying beneath it the cable leading to the motor which drove the hauling drums. There was some doubt whether the set of tubs was in motion in the shaft or not at the time of the explosion, but there was agreement that dust was present, and that a full set of tubs had been hauled out against the intake air current. Among the possible means of ignition were considered open lights, shot-firing, electricity, and sparking from mechanical friction. The report concludes with a confession that it was impossible to say which of these causes initiated the explosion; but the mechanical friction theory was accounted to be untenable in view of the experiments carried out by a sub-committee of the French Firedamp Commission, who failed to ignite marsh gas and firedamp by the sparks from a mechanical drill working against hard stone, or by a dazzling arc or continuous shower of sparks formed by pressing a bar of steel against a rapidly revolving emery wheel.

The cause of the Wellington Pit fire which occurred in May of last year is not absolutely determined in the Home Office Report, but the conclusion is that "although there is every probability that it is attributable to a safety lamp—which may have been either in perfect or defective condition—there is not sufficient evidence available to enable any one safety lamp to be indicated." In an appendix, Mr. J. B. Atkinson states his opinion definitely that fire-damp was ignited by the flame of one of the safety lamps, and Professor Galloway says with equal certainty of expression that the fire-damp was ignited at a damaged or defective safety lamp. If the opinions of these experts are accepted the theory of ignition by friction-gear must in this case also be abandoned; but, nevertheless, the evidence and the plans that accompany the Report deserve examination by all who may study the problem of ignition in mines, for in this instance the mechanical haulage plant is described, and the position of the friction gear is shown. The fact that fire occurred in certain regions of the mine and not in others cannot, of course, be attributed to anything relating to the plant. This distribution was no doubt the result of the corresponding local chemical constitution of the mine gases, and the explanation is to be found in the Home Office Report of 1896 upon the causes of death in colliery explosions and underground fires, where it is pointed out that in most fire-damp explosions there must be, in parts of the explosion, insufficient oxygen for complete combustion.

Lines of Progress.

Thus on the whole the friction-gear theory of ignition lacks positive support, and all that can be said is that there is enough possibility of danger to justify reasonable restrictions against the use of imperfect brake mechanism. The systematic testing of metallic brake shoes for train wheels has been in operation for several years, and elaborate and powerful machines have been installed for testing at peripheral speeds up to 80 m.p.h. These machines are fitted with self-recording apparatus for giving diagrams of pressure and speed, and account is taken of the wear of the wheels and shoes in each test. Advance has also been made in the direction of providing materials which reduce sparking and dust, and it is claimed that some of the new brake-blocks possess these characteristics in a marked degree.

If a research should be undertaken regarding this question of ignition by mechanical sparks the investigators would probably find some help from analogies with what has already been achieved in respect to electric spark ignition, and at certain points the two sets of phenomena may converge. The relationship between electric spark potential and sparking distance with change of air pressure, the effect of slight impurities on the minimum sparking distance, and the change in the electric field caused by the spark itself are all suggestive of lines of research with mechanical sparking. Lastly, attention may be directed to the significant words of Bichel that "all explosives require some initial impulse in order to explode," and to the effect of detonation in accelerating combustion.

OBITUARY.

Mr. N. F. McNaught, who had been identified with mining in the Slocan district of British Columbia for eighteen or nineteen years, died at Silverton, Slocan Lake, British Columbia, on May 12. He arrived at Ainsworth, B.C., in 1892, and the following year removed to Silverton, where he had resided ever since, up to the time of his death. He was part owner of several well-known mining properties, including the Alpha, about Four-mile Creek; the Hampton, on Springer Creek, and the Kilo, on Lemon Creek, all in the vicinity of Slocan Lake. In his numerous mining activities he was energetic, and in several successful. One of his characteristics was the erection of substantial mine buildings in his several mining camps. His body was interred at Everett, Puget Sound, Washington.

The total exports from South Africa amounted in 1909 to £51,151,463. Of this total, the mineral industry contributed 80.8 per cent.

SUMMARY OF PRINCIPLES IN THE SEPARATION OF ASBSETOS

Extract from Monograph "Chrysotile Asbestos," by Fritz Cirkel, M.E.

Although the method applied in asbestos separation is practically the same in every mill, no two mills are built alike. The serpentine in the different localities varies in hardness and toughness; one quarry extracts Nos. I. and II. grade by hand; another only No. I. grade; while others have abolished hand cobbing entirely, and send the whole output of the quarry through the mill. In some mills two qualities are produced; in others four or sometimes five. These factors, combined with other minor considerations, dictate to a certain extent the course of the treatment which has to be followed, and the kind of apparatus to be employed.

In order to illustrate the working of the serpentine method generally adopted, a description of a typical mill is given, which, by reason of its simple construction, will, it is hoped, facilitate the study of the principles involved.

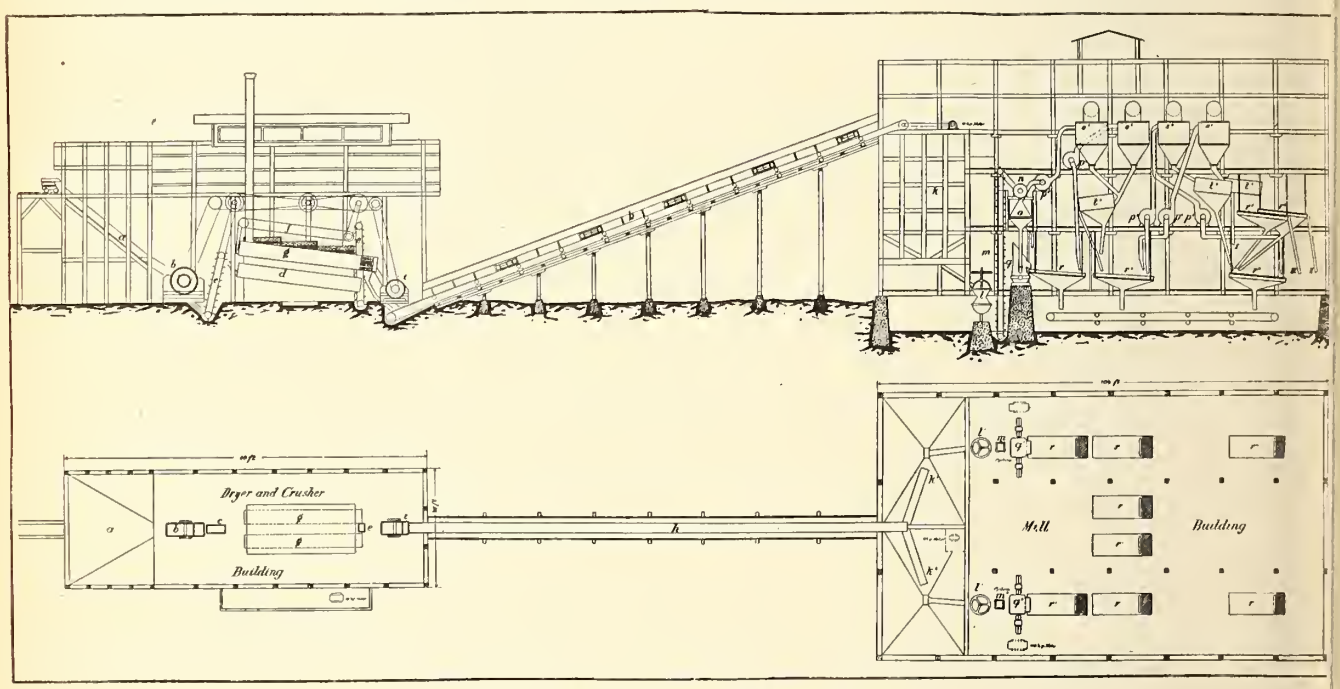

Fig: 36. Modern Asbestos Separation Plant.

A plan showing the arrangement of this mill is given in Fig. 36. No. I. and No. II. crude are hand-cobbed, and the balance of the asbestos material is sent to the mill for treatment. The serpentine used is massive, and of the usual hardness as found in the Black Lake and Thetford districts. Two qualities are made in the mill, with an additional grade out of the tailings of the shaking screens.

FIRST PART OF SEPARATION.

All the asbestos rock and fines produced at the mines are dumped into ore bin (a), then crushed in jaw breaker (b), raised by means of bucket elevator (e) to a chute, which empties into rotary dryer (d). A bucket elevator (e) raises the material to a belt conveyer (f), transporting it back to the other side of the dryer and delivering it to the second dryer (g). The end of latter is perforated, and effects a division of the r into "medium" and "rough." The "rough" is ag crushed in a second jaw breaker, while the "mediu or undersize falls directly upon the belt conveyer (which also takes up all the crushed material from breaker. The belt conveyer then delivers all the crus material to two ore bins (k^1) and (k^2), which discha through an automatic feeder to the Butterworth Low crusher (1). A bucket conveyer (m) dischar the rock into a fiberizer (n), and after thorough dimi tion the material falls on a screen (o), where a fan (takes up all the liberated fibre and deposits the sa into collector (s^1). The residue from screen (o) is delivered to cyclones (q); the discharge of the latter thrown on screens (r^1); here two separations of s and fibre are effected, the fibre being taken up by (p^2) and deposited into collector (s^2), the sand di pearing under the screens into a hopper, which emp on the sand conveyer (u).

SECOND PART OF SEPARATION.

All fibre extracted from the rock is now placed in leetors (s^1) and (s^2). From here, it passes throug grading screen (t^1), having arms within, moving in posite directions. In this screen two grades are m long fibre thrown on screen (r^2), and short fibre undersize) thrown on screen (r^3). These screens e a partial separation of the sand from the fibre; former falling on the sand conveyer (u) and the la being sucked up and placed into collectors (s^3) and From collector (s^3) the fibre is again screened in volving screen (t^2), the oversize constituting now

I., and the undersize being again treated on an os-ating screen (r^4) in order to get rid of the sand. atever fibre remains on this screen is taken up by a (p^5) and is deposited in collector (s^3).

he No. II. fibre which is in collector (s^4) goes ough the same process of clearing as the No. I. fibre, cribed above, and the final results are a Nos. II. and II. grade, in addition to the No. I. grade referred to.

he following chart, No. I., represents in graphic fom a summary of the foregoing descriptive outline of th various stages through which the longer fibre has to pss before it is ready for the market.

here are various other combinations, as will be seen fm the mill schemes laid out in charts II., III., IV., a V., and, furthermore, new combinations may sug-t themselves.

CHART I

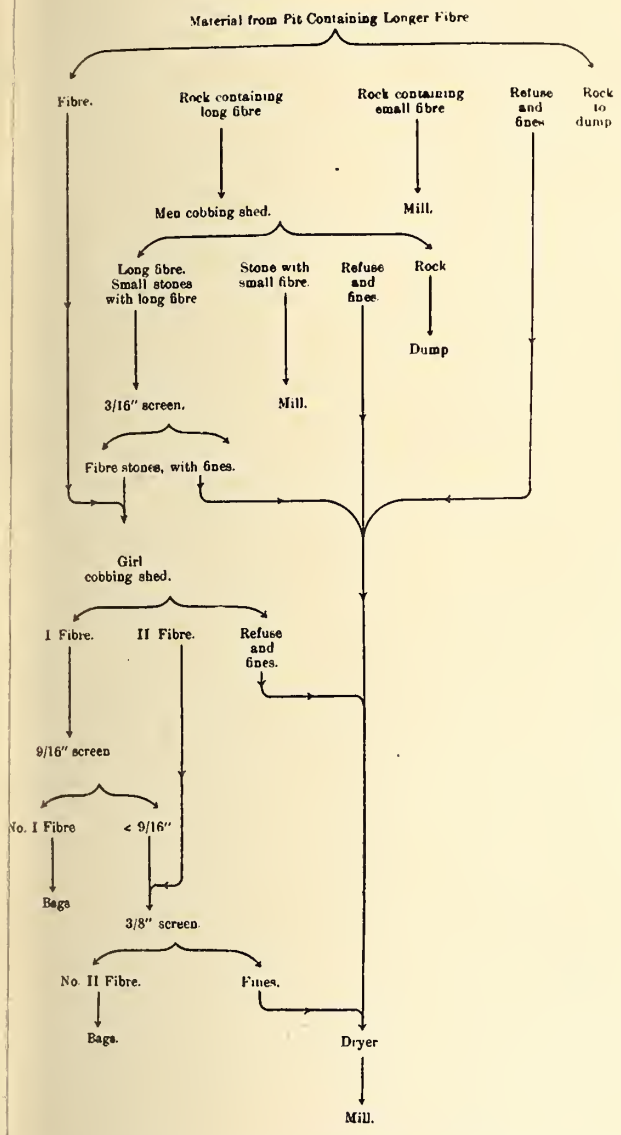

CHART II.

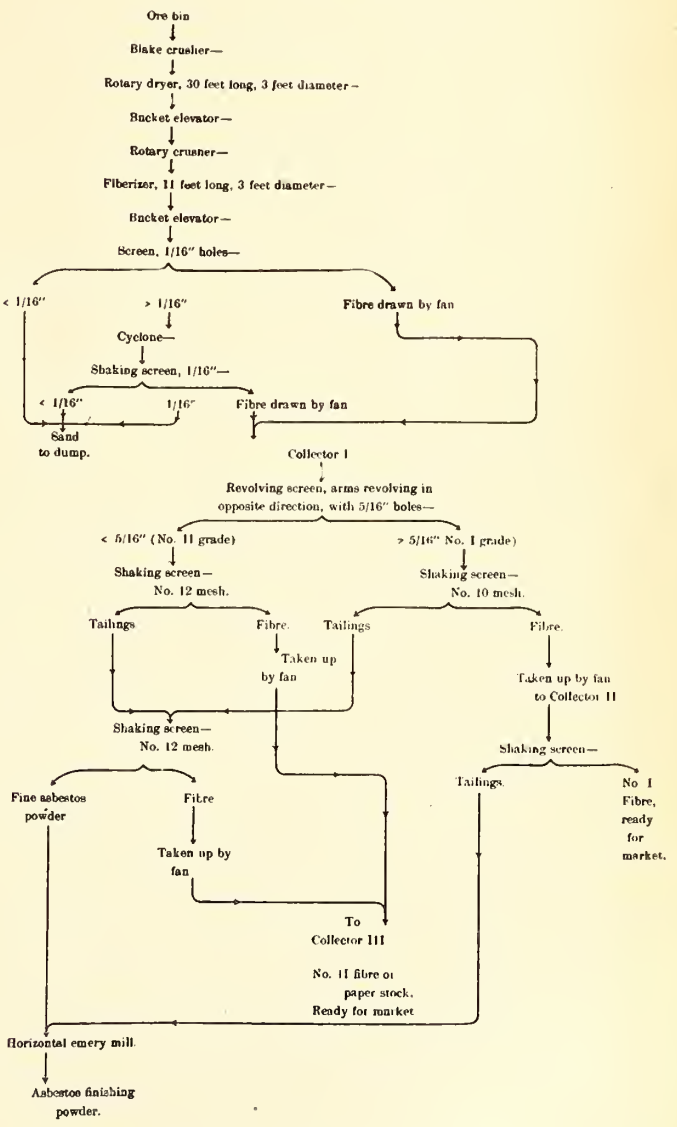

Theoretically, the principles introduced would allow perfect separation of all the asbestos from the rock, d of the different grades; but practically this is very fficult to accomplish, and is rarely attained.

In looking over the above-mentioned charts, we find at the principal object in the first stages of the pro-ss is to eliminate the sand through the shaking screens, d to have as much fibre taken up by the fans as is practically possible. We learn also that many combinations of the crushing machinery are used; but the jaw crusher always forms the initial step, followed by a rotary or Gates crusher; while the last stages of the process are practically the same in all the mills, with very few deviations.

In mill IV. a picking table is inserted between duplex crusher and elevator. These picking tables consist of an endless rubber belt of a width varying between 18 in. and 24 in.; and turning on a wide cone or pulley, with a length of from 12 to 18 feet. Boys are stationed along the belt, picking up the dead rock, long asbestos fibre, and pieces of iron, or rubbish which may have fallen accidentally into the ore. In mines which produce much crude, this arrangement is very important, as the long fibre which was hidden in the rock before breaking can be removed and saved as crude. It is also of equal importance that all the rock which contains no fibre be taken out, to relieve the subsequent operations from unnecessary work.

In the extraction of pieces of steel and iron from the ore powerful magnets are employed. An effective design for this purpose is in use in some of the Montana mines[1], and its adoption in the asbestos mills of Quebec will not meet with any difficulty. The magnet can either

be placed over the conveyer belt, or over the shaking screens. The metal to be removed consists of pieces of steel, bolts, track spikes, and castings from the machine drills; in fact, any iron that may get into the ore on its way from the stope to the mill.

The magnet used consists of a cast-iron part (a) 4 in. thick, 20 in. high, and 20 in. wide. It is wound with 19 layers of No. 10 double cotton-covered copper wire (c), with 2,300 turns on each pole. The current used is 5 amperes, at 125 volts. The pole faces (b) are 2 in. x 6 in. x 24 in., and are spaced 6 in. apart. The magnet is suspended from a carriage (e) and supported on a track (d) at right angles to the belt. When a number of pieces of iron are collected on the magnet, the entire apparatus is moved to one side, the current cut off, and all the iron is dropped to the floor. The magnet is suspended 6 in. to 8 in. above the belt, and is adjustable by the means of turnbuckles (f). This magnet will pick up pieces of steel weighing as much as 10 pounds; this prevents trouble and breakage at the rolls.

CHART III.

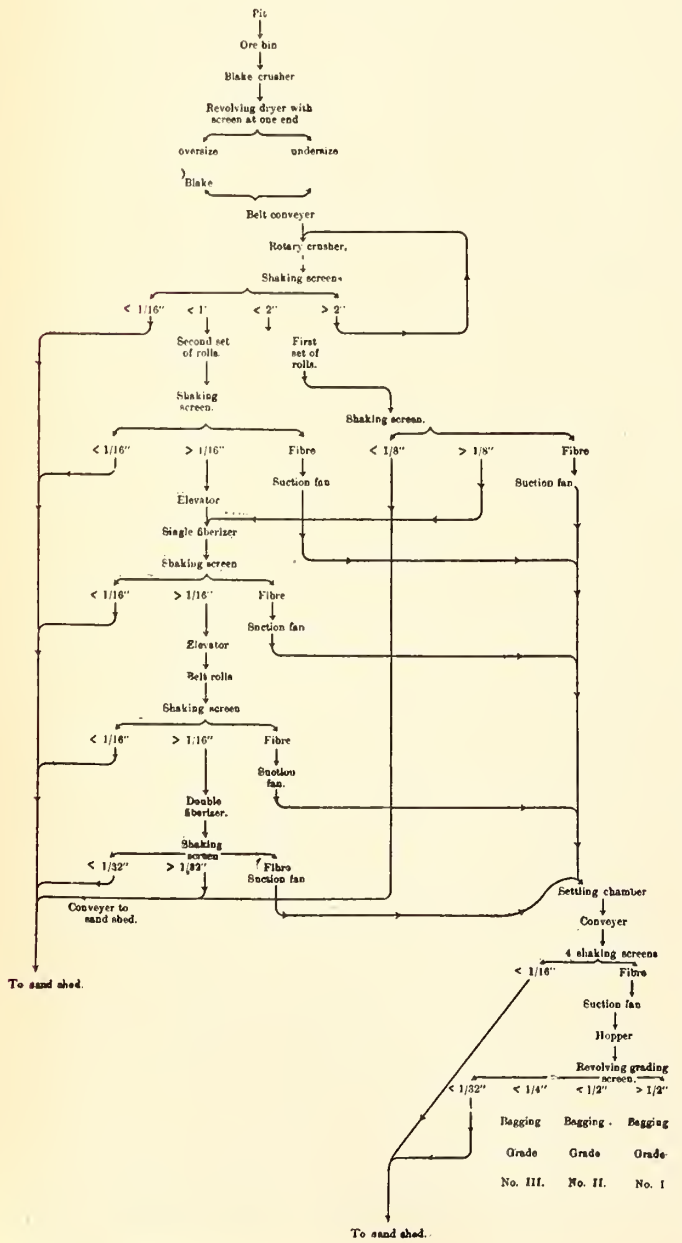

CHART IV.

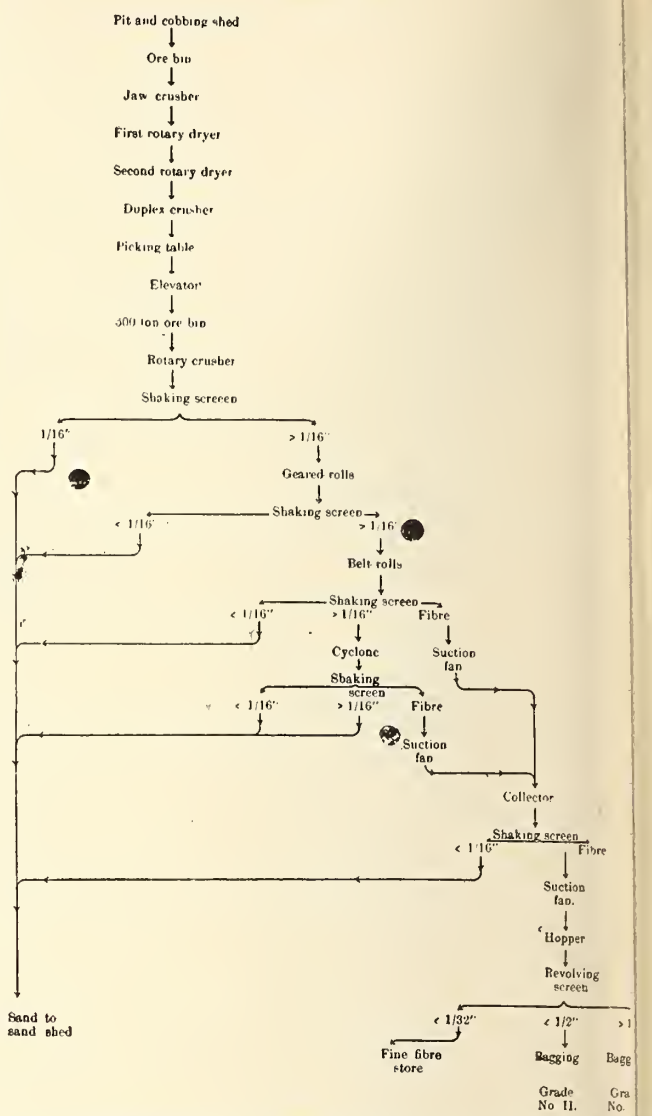


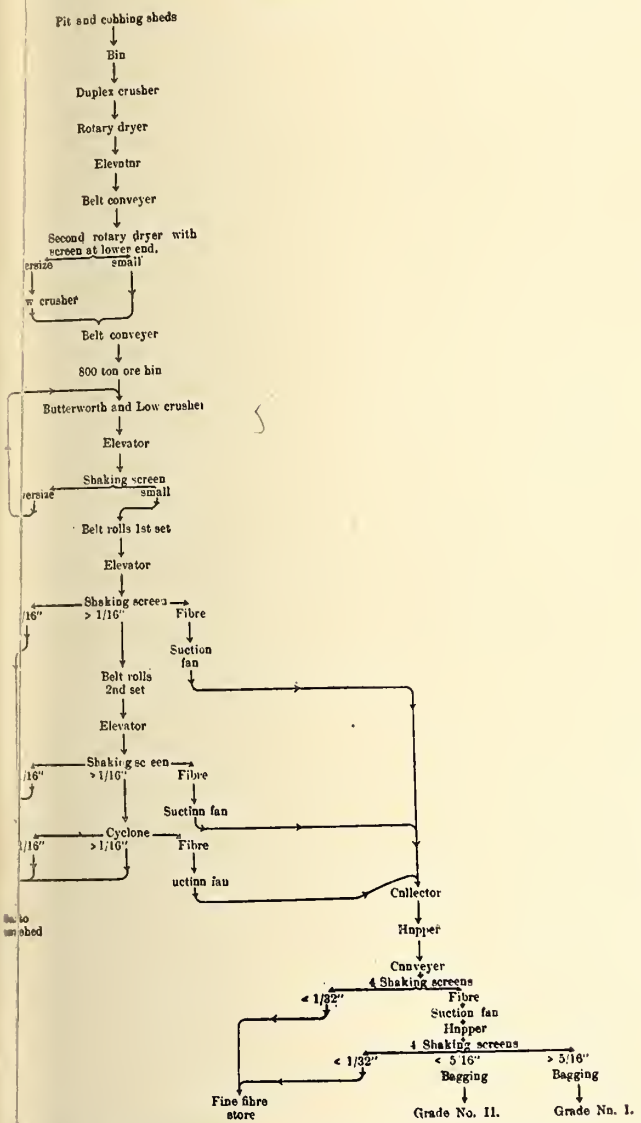
In designing a mill, due attention must be given p- cipally to the crushing department; since mistakes m- e here have very serious results, either in the quality f the fibre produced, or in the low percentage of ext- tion. Experience shows that crushing of the rock be- e drying is absolutely necessary in order to ensure c- plete drying of the rock in wet seasons. As a gen- l rule, one or even two Blake crushers are placed be- e the dryer, and one at the discharge end of the lat- r. The drying and most of the coarse crushing is now ll done in a separate building; because, when placed in e upper part of the mill building, the power toggle m- ment of the jaw breaker causes a heavy vibration in e structure of the building, hence, heavy construction is necessary. A new departure in mill construction may be seen in the plant of the Robertson Asbestos C- pany, between Robertson and Thetford stations. H- e the whole plant is divided into three parts: the dr r and crusher building; the re-crusher; and the cycl- e building. This is the first time that this division n three separate departments has been made.

There are other new noticeable features in this n- l. The rock coming from the dryer passes through o gyratory and one rotary crusher, having shaking scre- s between, for the purpose of abstracting, by means f suction, whatever fibre there has been liberated thro- h crushing. We notice that the rock passes through t

han five different crushing apparatus before it enhe cyclone; and three in nearly all other mills; it y exceptionally that four crushing machines are for the same purpose. It is urged in support of novation that the cyclone, which receives only ore iform size—smaller than a walnut—will treat a gher tonnage of ore, doing at the same time, better nore uniform work.

There can be no question that through the employmen of the designs indicated above, the efficiency of a mills increased; while much breakage in the different pieces of apparatus—especially in fast revolving machines like the cyclone—is prevented.[1]

CHART V.



f the fiberizing machines the cyclone appears to be th most extensively used in the mills. In some of the ne er mills other machinery has been introduced to take th place of the cyclone. This is shown on chart for mi l No. III., where the fine crushing is represented as be ng done by two pairs of belt rolls, in connection wi h single, and double cylindrical, fiberizing apparatus. In another mill the material passes twice in succession th ough a set of rotary crushers and a beater of recent design; the construction of which is kept a secret. It is claimed for this new departure that the fibre is not torn up so much, and that the repairs are less, and not so costly as those in the cyclone machines.

The different grades of fibre are, as a rule, made in most of the mills at the end of the process, by sizing in shaking screens, or in revolving screens, with arms moving in opposite directions. A new departure in the extraction of the fibre from the screen, and the elimination of the sand, was made several years ago in a mill of new construction. The experiment failed; but for the novelty of the idea, and for the purpose of calling attention to the mistakes involved in its application, the device is again described and illustrated. The material after being crushed successively in a jaw and rotary crusher,

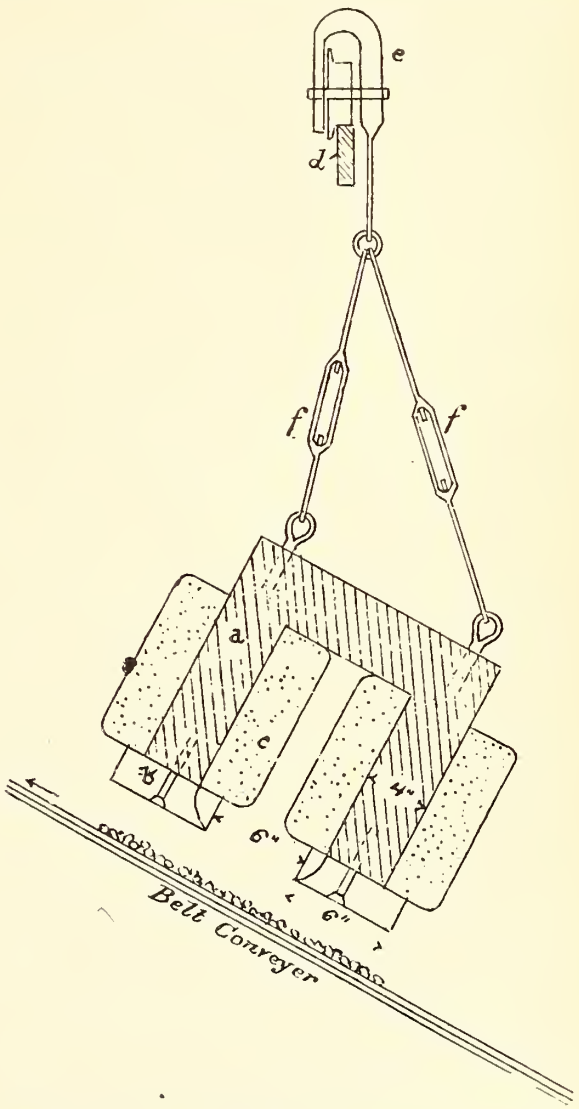


FIG. 42.—Magnet for picking steel from ore.

and a beater, falls on a double shaking screen, as illustrated in Fig. 43: the upper one having 7/16 in. and the lower one 1/16 in. mesh, allowing the sand to pass away. The fibre is graded in this way into No. I. and No. II. Each grade is taken up at the end of each screen by suction fans, and deposited in separate collectors. The overflow from both screens passes again through a rotary crusher and beater and a double screen as before; while the two grades of fibre, so produced, are taken up and deposited in collectors. The principal trouble in this device was the difficulty of

[1] Since writing the above several changes in this mill have been made, and at the same time the capacity increased from 2 to 6 cyclones.

gaining access to the lower screen: it was blocked so frequently that its usefulness soon vanished.

The sand from all the shaking screens falls generally into a long hopper, having a rubber belt conveyer at the bottom, which transports all material to the outside. Where the dumping ground is not on the same level with the mill, the sand is carried by conveyers into elevated sand-sheds or large reservoirs, from which cars are loaded and sent to the dump.

At the British Canadian quarries the sand is transported through a 658 ft. rubber conveyer to the dump; from thence it is carried away through sluicing; a turbine pump actuated by a 75 horse-power electric motor placed at the river bank furnishing the necessary water through a 6 in. main 1,000 feet long, to the top of the dump.

In the mills at Danville the bulk of the sand and tailings from the shaking screens is manufactured into *asbestic*: a fine asbestos powder which enters now largely into the construction and inside finish of fireproof buildings.

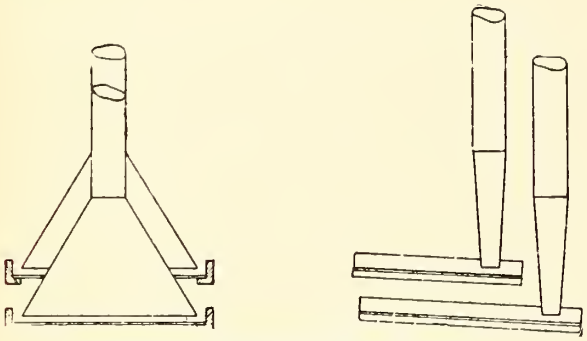

FIG. 43.—Double Shaking Screen.

In one of the largest mills recently erected, all the tailings are pulverized in giant, vertical, Emery mills.

GENERAL FEATURES OF THE MILLS IN THE DISTRICT.

With a few exceptions, the mills visited by the writer are located near the quarries: that is, within 500 feet; indicating that the transportation of the ore to the mill is a most important factor. In the general arrangement of all the newer mills due consideration has been given to the dumping ground, with a view to preventing the covering of valuable ground. For this reason the mills have been built away from the quarries.

With regard to the sites on which mills are built, we may distinguish between (1) a sloping or terraced site (Fig. 44); a flat site (Fig. 45). In the former case advantage is taken of the sloping condition of the ground, all material being conveyed by gravity, and heavy elevators are few. An example of this kind is the old mill of the Union quarry, now of the Black Lake Consolidated Asbestos Company at Black Lake.

Mills on the flat ground, however, are the common rule. The disadvantages are, that more elevators are required; which wear out rapidly; causing stoppages of the mill on account of breakage, and annoying the mill man.

An asbestos separation plant is usually designed in the form of a three or four-storey building. The ore is received in a large ore bin, placed in the upper part of the building, or in an annex: allowing the ore to pass through the crushing machinery by gravity; elevators being used between the apparatus for middlings and for recrushing. In the majority of cases, however, the passes on straight without recrushing in the same paratus. Sometimes all the fine crushing apparatus fiberizers are placed in one line and on one floor, as the mill of the Johnson Asbestos Company at Bl Lake. Small elevators convey the material from apparatus to another; and it is claimed for this arran ment that the machinery can be watched better, and

(b) Dryer (d) Storehouse.

more accessible than when placed on different lev The screens receiving the material from the crush are, as a rule, placed all on one floor, for the purp of greater accessibility; while an endeavour is made do the same in all the newer mills, with the shak screens for the fibre.

In mills of recent construction—in order to av complete stoppage caused by breakage of machinery otherwise—the whole milling plant is divided into portions, and constructed on precisely the same li but run independently of each other. This innovat was noted in the mills recently built at East Brough

(b) Elevator. (e) Sand shed.
(c) Mill. (f) Elevated track

and at the "British Canadian" quarries. In the la this principle is even carried further: the two secti are again divided into different parts, each one emb ing a certain group of machinery run by special elec motors. In the mill proper the six cyclones are placed in one line on one side of the building; the e tric motors actuating the same being all in one separ compartment close by. This is an arrangement of paratus to be recommended on account of its great eessibility, uniform division, and the protection of motors against flying dust.

At the extraordinary general meeting of the C tral Mining & Investment Corporation, Limited, h at No. 1 London Wall buildings early in June, capital of the company was increased to £5,100,0 sterling. The agreement between the Central Min & Investment Corporation, Limited, and Messrs. We ner Beit & Company, and Messrs. W. Eckstein & Co pany, which provided for the purchase of several the assets of these two well known mining firms, a which had previously been unanimously confirm was brought to completion. The committee appoin to value the assets taken over were Messrs. R. T. B liss, Otto Beit and G. Rouliot, and the values m by them were accepted. Three representatives of French shareholders were elected to the board.

New Dominion Copper Company, Ltd.

The new Dominion Copper Company, Ltd., owns several groups of mineral elaims, situated in the Boundary Distriet of British Columbia. A controlling interest in the eompany's eapital stoek is held by the British Columbia Copper Company, so its mines are operated under the same local management as those of the atter eompany. Mr. J. E. MeAllister, of New York, formerly general manager, is now consulting engineer, and Mr. E. G. Warren, of Greenwood, is aeting general manager. The partieulars that follow have been taken from the eompany's second annual report:

Report of Directors.

Under date New York, June 5, Mr. Newman Erb, vice-president, reported to the shareholders as follows:

During the fiseal year ended March 31, 1911, the activities of your eompany were direeted principally to the development of the Rawhide and Athelstan mines. Incidental thereto, there was extraeted 90,000 tons of ore, of which more than 30,000 tons eonsisted mostly of waste left in the mines during former operations and about an equal tonnage in very low-grade ores, all neeessary to be removed as part of the development work. These mines have, with the end of the fiscal year, just reaehed the stage for normal operation, when reasonably profitable results may be henceforth expected.

The net expenditure during the fiseal year was $16,472.59, whieh is within the estimate originally submitted by the company's engineer before the development work was begun. Beside, this amount ineludes administration, office, legal, and other expense.

On January 2nd last a fire destroyed the offiee, machine and repair shops, supply building and eontents at the Rawhide mine, entailing a loss of $26,546.97, covered by insuranee to the amount of $25,000, whieh has since been eolleeted.

'The eompany acquired $16,150 par value of its bonds, whieh are now in its treasury. While no ineome was available for the payment of bond interest during the year, your direetors believe that the operations for the coming year, under normal conditions, will result in sufficient ineome to provide for its payment.

'It is intended now to diamond drill and thoroughly explore the Montezuma and Sunset mines in the expectation that they will develop as substantial producing properties.

'The past year has been extremely unfavourable to the eopper industry the world over. These eonditions appear to be approaching a marked ehange for the better, and, with the expeeted improvement in the market value of the metal, substantial gains in operating results will naturally follow. While eonditions have been discouraging, we are now justified in eonsidering them as more hopeful.

"The exeeutive is indebted to the general manager and the operating foree for their intelligent eo-operation, zeal, and fidelity."

Handling loss, 0.25 per cent..	718.83	
Net value		$ 77,895.29
Less freight		22,722.71
		$ 55,172.58
Proceeds of ¾ interest in ore shipped from Mountain Rose mine		44.22
		$ 55,62[illegible]80

Schedule B—Rawhide Mine Expense.

Analysis of Rawhide mine expense for year e[illegible]ed March 31, 1911:—

Preliminary development		$ 10,63[illegible]3
Mining expense		58,45[illegible]0
Development—		
Drifts and cross-cuts	$14,045.92	
Raises and winzes	17,586.67	
		31,63[illegible]
General underground		26,83[illegible]0
Tramming and bins		2,15[illegible]5
General surface		11,13[illegible]
Construction		96[illegible]
Addition to stable	$253.07	
Addition to blacksmith shop..	174.23	
Dry house	84.90	
Carpenter shop	190.01	
Transformer building	208.86	
Miscellaneous	51.09	
Deficit on preliminary shipments ore		3,04[illegible]
		$144,87[illegible]
Less ore in transit March 31		1,814[illegible]2
		$143,061[illegible]0
Net loss on supplies destroyed by fire		1,54[illegible]7
Taxes accrued due		2,86[illegible]0
		$147,468[illegible]7

MINERAL PRODUCTION IN ONTARIO, FIRS[illegible] QUARTER OF 1911.

Returns to the Bureau of Mines show the follow[illegible]g production from the metalliferous mines and works [illegible]f Ontario for the three months ending 31st March, 19[illegible]

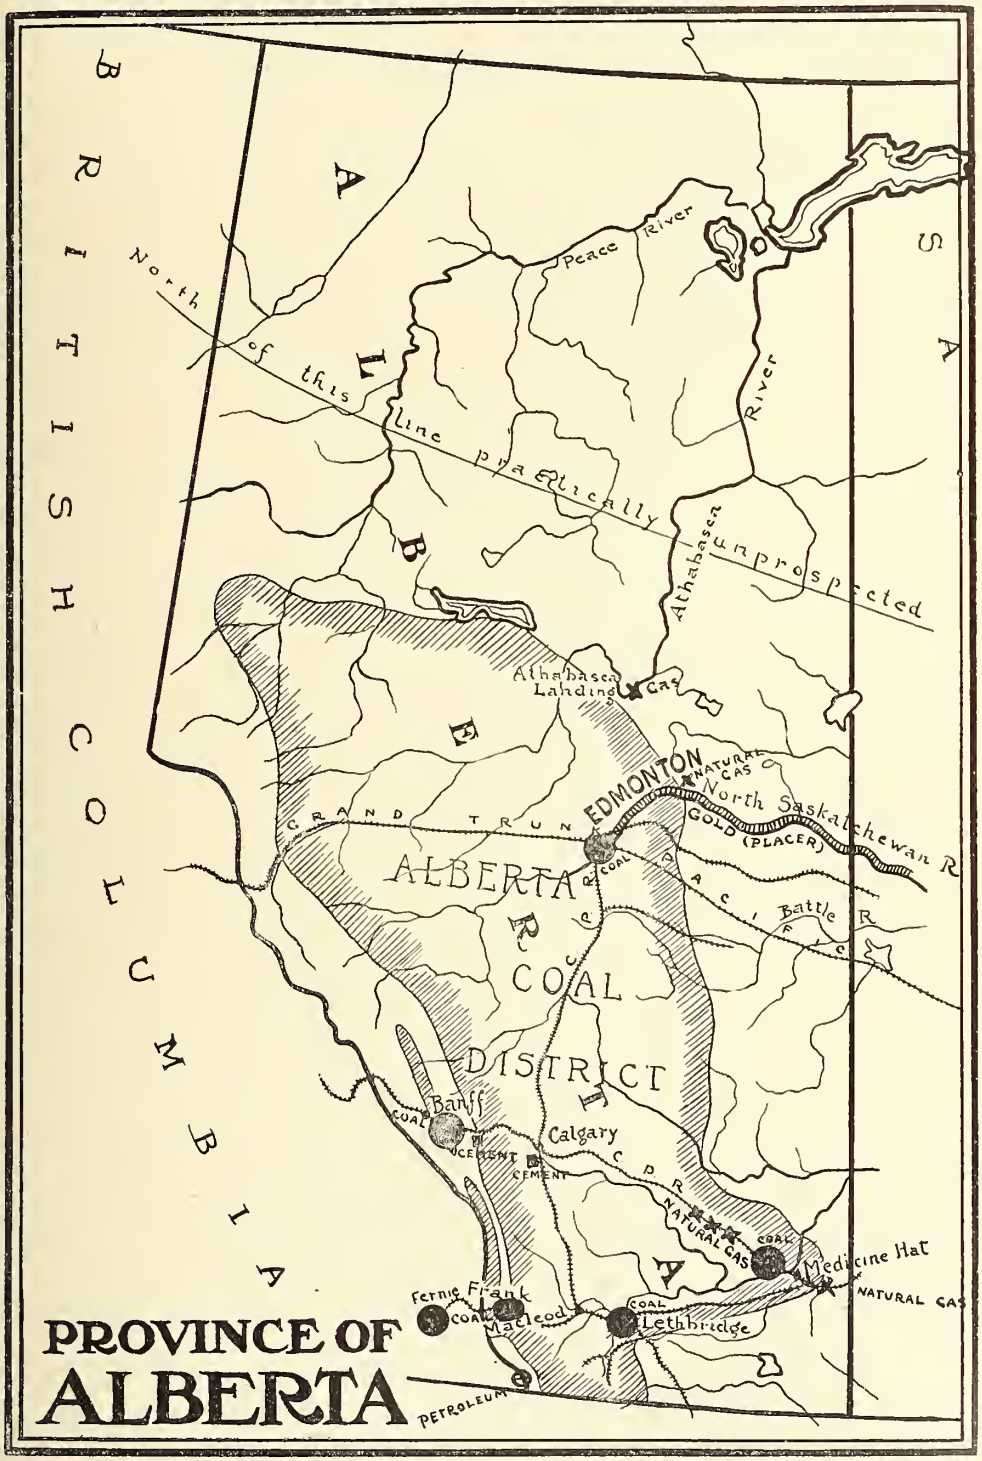
	Quantity.	Valu[illegible]
Gold .....ounces	1,813	$ 33,[illegible]0
Silver .....ounces	7,530,487	3,708,[illegible]4
Copper .....tons	2,121	303,[illegible]0
Nickel .....tons	4,124	884,[illegible]2
Iron ore .....tons	11,621	24,[illegible]4
Pig iron .....tons	115,454	1,823,[illegible]7
Cobalt and nickel oxides..lbs.	107,846	29,[illegible]2

As compared with the first three months of 19[illegible] there is a decrease in copper and nickel from $357,0[illegible] and $1,131,024 respectively, and an increase in iron [illegible] from $15,034, pig iron from $1,750,396, and in silv[illegible] from 6,399,927 ounces, valued at $3,041,158.

The somewhat serious shortage of electric power [illegible] Cobalt during the quarter might have been expected [illegible] lead to a reduction of the silver output, and althou[illegible] power is now again plentiful the effects may perha[illegible] be seen when the returns for the second quarter of t[illegible] year are received. Gowganda and Elk Lake produc[illegible] 132,900 ounces of silver during the quarter, and Sou[illegible] Lorrain 66,795 ounces. The total shipments from C[illegible] balt were: ore, 3,786 tons; concentrates, 1,974 ton[illegible] bullion, 2,004 pounds.

The Rocky Mountain Collieries, Brazeau Collieries, and Sixth Meridian Coal Lands.

Notes from the privately circulated Report of Chas. L. Hower, M.E.



EDITOR'S NOTE.—Through the courtesy of one of the directors of the above companies the CANADIAN MINING JOURNAL is permitted to give the following notes from Mr. Chas. L. Hower's excellent report. For some years Mr. Hower has been working in the coalfields of Alberta. His report is singularly careful and accurate.

The three groups of coal lands mentioned above are owned conjointly by Mackenzie & Mann and the German Development Co., Ltd.

Most of the property is held outright, the coal purchased, and the mining rights perpetual. Some of it is held on approved leases, with the title still pending.

All areas owned were purchased from the Government. The rights are perpetual. Ten cents per ton will be payable to the Government on all coal mined.

The leased properties are in the National Park, where special regulations are in force, or in territory acquired under the new mining regulations. These properties are held on twenty-year leases at a cost of one dollar per acre per year and a five-cent per ton royalty for coal mined.

The ultimate divisions are as follows:—

Rocky Mountain Collieries, Ltd., Kananaskis Field, coal leased, 5,440 acres.

Brazeau Collieries, Ltd., coal owned 10,320 acres, coal leased, 5,480 acres; surface, 640[1], 200[2].

Sixth Meridian Coal Lands, coal leased, 4,480 acres; surface, 6,400[3] acres.

History.—Most of the Province of Alberta is underlaid with coal; but east of the Rockies the accessible deposits are recent lignites. The Cretaceous measures carrying the true bituminous coals are under many thousand feet of cover, and only at points where the measures are thrown up in the mountain ranges are the deposits brought to the surface. And only in certain protected localities have the measures been preserved from erosion.

The existence of coal in the Kootanie series of rocks has been known for some years, and coal has been mined extensively in the Crow's Nest Pass and near Banff. Coal in the same measures in the mountains to the north was discovered by Mr. D. B. Dowling, of the Dominion Geological Survey in 1906. In 1907 Mr. Dowling's services were secured by the managing director of the German Development Company, and prospecting and staking commenced. Three fields, the Saskatchewan, the Bighorn, and the South Brazeau were staked. The Kananaskis field was staked in the National Park south of Banff.

In 1908 Mr. Dowling returned to the Survey, and Mr. James McEvoy, formerly chief engineer to the Crow's Nest Pass Coal Mining Co., was engaged. Under Mr. McEvoy's direction the territories mentioned above were thoroughly prospected, and, in 1909, the Race Creek field was staked. At the same time Thomas Russell staked the McLeod and Main Brazeau fields for Mackenzie and Mann. Later, Russell staked the Sixth Meridian Coal Lands. In 1909 the holdings of the German Development Co. and those of Mackenzie and Mann were amalgamated.

Rocky Mountain Collieries, Limited—As noted above, the property of this company consists of 5,440 acres of leased coal lands in the Canadian National Park, mainly on the west side of the Kananaskis River, about 12 miles above the junction of that river with the Bow River. Sections of the coal measures have been opened at three points, first near the southern end, second near the middle of the property on Ribbon Creek, and third near the northern boundary. The coal is known to run continuously through the property, but sufficient work has not been done to establish the identity of the seams at the various points. Neither are the seam intervals uniform. The various and excessive dips are difficult to measure and to project. Basing an estimate on the coal in sight, the property contains 415,800,000 tons, figuring the workable thickness of the various seams at 50 feet. The analyses indicate a semi-bituminous coal, rather high in ash owing no doubt to the surface dirt in the samples taken near the crop.

The following proximate analyses show the character of the coal sampled on seams Nos. 5, 7, 8, and

	5	7	8	
Moisture	0.72	1.50	2.82	0.
Volatile	16.34	11.79	19.33	12.
Fixed carbon	71.89	69.66	65.70	73.
Ash	11.05	17.05	12.15	12.
Sulphur	0.87	0.79	....	0.

Mr. Hower's estimates of production costs ran from $1.37 to $1.56, depending upon whether da outputs of 3,000 tons or of 1,000 tons be aimed at.

Brazeau Collieries, Limited.—The six areas of t company lie almost in a continuous straight line a extend from the southern banks of the North S katchewan River in a northwesterly direction to t headwaters of the McLeod River.

The company owns in the six fields of Saskatchew Bighorn, South Brazeau, Race Creek, McLeod, a Main Brazeau, a total of 10,320 acres of coal lan holds 5,480 acres under lease, and owns surface rig on 560 acres in South Brazeau. From 17 to 21 wo able seams of coal are known. The total workal thickness ranges from 13 feet in Main Brazeau up 60 feet in South Brazeau. The total quantity of c is estimated at 612,000,000 tons.

Nearly all the seams are coking coal. The a which is higher than normal to the unweathered co runs from 8.43 per cent. to 14 per cent. Volatile co bustibles are reported as low as 22.29 per cent., a as high as 32.30 per cent.

(To be continued).

The scope of the diamond drill does not include dr ing in such rock as limestone containing chirty nodul Highly inclined and flinty rocks are also dangerous t the diamond drill, as the loss of diamonds is apt to excessive. The calyx drill is cheaper in soft or mod ately hard material, but it is not adapted to bori holes at an angle greater than about 25 degrees fr the vertical. The shot method is more efficient than t calyx in hard ground, but is not adapted to soft m terial. It may, under proper conditions, be used f boring holes at any angle.

"The Yukon Territory is likely again to become c spicuous financially by reason of a new venture bas on gold-bearing gravel deposits in the Klondike d trict. A syndicate, with a capital of £200,000, has be formed by Messrs. H. C. Hoover and A. C. Beatty, ha of the amount being placed in New York and half London. The intention is to bring out a company lat with a view to exploiting a number of claims situat on Dominion, Quartz, Last Chance, Eldorado, and oth famous creeks near Dawson. The vendor is Mr. A. N. Treadgold, well known in connection with the Yuk Gold Co., an enterprise controlled by the Gugge heims. The money now raised is, we understand, to loaned to Mr. Treadgold, who, in return, gives the sy dicate the call on his rights, with a view to an issue, wh it is deemed expedient. The property has been examin by Mr. W. E. Thorne, who has submitted a favourab report."—From the Mining Magazine, London.

[1] Owned. [2] Leased. [3] Pending.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

mion Coal Output.

Th outputs for the first half of June were very satisfactory. alth igh the output capacity of the mines is not quite as large s it was in 1908, the production is gratifying by reason of its stea uniformity, and the fact that it is all obtained on single-shif working. For the first twelve days of the month the outp t averaged well over 14,000 tons per day, which it at the rate f 370,000 tons monthly. During the latter half of the mon there will be some reduction owing to the provincial elec ons on the 14th, and the effect of Coronation Day. Shipmen were also unusually rapid. During six days over 70,000 ton were shipped over the International Piers at Sydney for St. awrence ports.

Colliry Wash-Houses.

Th subject of the miner's bath has given rise to a large amo nt of discussion in the British Isles of late. It has always bee a matter of surprise to mining men from the Continent of urope to find that British miners are in the habit of returning to their homes from the pit without washing or changing their clothes. The person who suffers most from this custom is te miner's wife, more particularly as the arrangements for taki g a tub in the majority of miner's houses in Great Britain are not of the best. It is certain that very little opposition will be forthcoming from the female relatives of the miner to mo adequate provision at the pithead for washing and hanging of clothes. The writer was for many years employed at colliery in England at which one of the first ''wash-houses'' at n English colliery was erected. The wash-house was designed after the German pattern, with shower-baths and clo es lockers, and it was welcomed by the younger miners. Amo g the older generation of miners, however, there lingers an idea that too much washing is weakening, and in one district of England at least it is regarded as distinctly unwise to wa the backbone. One old collier that the writer remembers, who scrupulously clean in every other respect, would not allow any water to be applied over his spine, but had that portion scrubbed clean with a dry cloth.

In Nova Scotia it has been the custom for many years to provide wash-houses fitted with clothes-lockers and facilities for cleansing the upper part of the body, and they are used by practically all the underground workmen. To see the miners' bath in perfection, however, one has to travel to Germany, although ''Engineering & Mining'' had recently an account of a fine wash-house on the German plan which has been provided at the Marianna mine in Pennsylvania.

In many of the German collieries the miner coming from the pit heated and perspiring, can walk directly from the pit mouth into the wash-house through a covered gangway, and is not exposed to the outside air. After his shower-bath with hot or warm water he can finish off with a cold shower, thus lessening the risk of catching cold. No one seeing the German miner on the street can tell, except by the dinner-can he carries, whether he is on his way to or from work, or whether he is merely out for a stroll. This is just as it should be.

The Coal Mines Regulation Act in Nova Scotia calls for the provision of a suitable house for changing and drying clothes at every mine employing more than 12 persons, and this is generally interpreted to mean also the provision of washing-bowls and running water. The last wash-house erected by the Dominion Coal Company at the Lingan Mines is a great improvement on its predecessors, and it is certain that so far as Nova Scotia is concerned, the colliery wash-house is not only a permanent institution, but one which will be improved as time goes on.

The following paragraph from the ''Engineering & Mining Journal'' of New York of June 10th may interest Nova Scotian and New Brunswick readers:

''At auction in New York, June 1, a lot including 950 shares Northern Coal Company, Ltd., of New Brunswick; 39,936 shares Kent Coal Company, Ltd., of Maine; 44,875 shares Crown Coal Company, Ltd., of Maine; 24,950 shares Great Northern Coal Company, Ltd., of Nova Scotia; 41,201 shares Great Northern Coal Company, of Maine; 960 shares North Shore Railway Company, of New Brunswick, and claim to title in 49,950 shares Maritime Coal Company, Ltd., of Nova Scotia, brought $10,500 for the lot.''

This is the aftermath of the wonderful prospectuses of Dr. Hugo von Hagan, to which reference has been made at various times in this correspondence and the columns of the ''Journal.'' It is more than probable that the person who spent $10,500 on the shares just mentioned paid all they were worth.

ONTARIO.

Cobalt, Gowganda, and South Lorrain.

While there has been a considerable falling off in the tonnage from the Cobalt camp, the first quarter's figures as published by the Government show that the silver ounces are higher than for the first portion of 1910. It is a striking illustration of the fact that tonnage plays little part now as an index of the prosperity of the camp. While there is no likelihood that any more mills will be built this year when that of the City of Cobalt is completed, the Crown Reserve and the Kerr Lake have signed contracts with the Nova Scotia and in a few months all their low grade tonnage will leave the camp by express and will not add one single pound to the ore freight carried by the T. & N. O. Railway. In addition the Nipissing is now reducing to bullion most of its high grade ore, and in a few months will have so completed its plant as to be able to handle all its high grade ore in this way. Cyanidation has increased at four mills, and the local sampling plant is every week turning out many bars for other mines.

It may now be said that the process devised by Mr. Butters for the Nipissing high grade ore is a commercial success, though it is by no means out of the experimental stage yet. The high grade ore is now being treated at the mill and reduced to bullion at a substantial profit above what would have been received had the ore been sent direct to the smelters. Mr. Butters is now endeavouring to discover a process whereby the low grade ore can be treated chemically with a high extraction and at a low cost per ton.

There is to-day more chance that Gowganda will have a railroad than at any time in the history of the Montreal River. It is hinted that the Porcupine branch will be extended south to tap some good farming land that has been located, and it is understood that it may be extended through Gowganda to connect with the Canadian Northern lines.

The recent development at the Millerett renders it likely that that property will be running with profit for its owners for many years. In their diabase area they now have an ore body 75 feet long on the 150-foot level which gives promise of a large quantity of milling ore. A vein about two inches wide, carrying 2,000-ounce ore, has just yielded a shipment of 30 tons of high grade ore. Outside this, in the country rock there is on either side of the vein a foot of good milling rock. The ten-stamp mill is now running and treating about 30 tons of ore per day. At the Miller Lake-O'Brien recent development at the 200-foot level has revealed an ore body which for richness and tonnage has not been equalled in the mine so far. All ore shipped out this summer has to be handled six times before it reaches the cars at Latchford, and nothing but the highest of high grade can be shipped at a profit.

At the Wettlaufer mine, now under the management of the Mines Finance Company of New York, it has been decided to erect a mill of about ten stamps to treat the large amount of low grade ore which has been accumulating since operations

commenced. Good ore has been discovered at the 120-foot level of the Bellellen mines in the same camp. The vein, very spectacular on the surface, was lost when the shaft had been sunk a few feet on it. There is every prospect that when the gold excitement has subsided a little that considerable attention will again be paid to this now neglected silver camp.

The Buffalo annual report for the year ending April 30 shows that a little more than a million and a half ounces of silver were produced, that there is now a cash surplus of $41,000 after paying dividends of $370,000, and that the ore reserves now stand at approximately what they did a year ago, namely, 4,000,000 ounces. The president reports that but for the shortage of power there would have been a considerable increase in the production of the mine.

The Beaver Consolidated has declared a second dividend of 3 per cent., or $60,000. The company has now paid $110,000 in dividends. It is expressly stated that this dividend is not a regular quarterly, but hope is expressed that later in the year the directorate may declare a regular rate. An additional force of fifty men has been employed to push development work and a new bunk-house has been built for their accommodation. The quarterly report of the Beaver for the three months ending May 31 shows that there was then on hand $96,241, out of which the dividend of $60,000 has to be paid in August.

The St. Lawrence Mining Company has recommenced work on the Sasaginaga Lake property. A crosscut is now being run from the 100-foot level to intercept the calcite vein which dipped out of the shaft.

The Silver Leaf shaft is now being put steadily down till the Keewatin, which has been productive on the adjoining Lawson, is reached. It has now reached a depth of 465 feet.

The Temiskaming Mining Company has declared another 3 per cent. quarterly, payable July 12th. When this distribution has been made the company will have paid 38 per cent., or $924,156. Exploration at the 575-foot level has so far failed to discover any tonnage of high grade ore, though several rich streaks have been drifted through.

Porcupine, Swastika, and Cripple Creek.

It is now possible to buy a ticket into Porcupine from Kelso though until next month no passenger trains will be put on and no time schedule is published. Excellent progress is being made with the railway and steel is now laid to South Porcupine, while the right of way is being cut towards the Hollinger mines. The Timmins-McMartin and Dunlap syndicate is financing the building of the extra four or five miles, the Government refusing to make the extension without some cash assistance. The Commission will get $175,000 from the mining syndicate to build the line, will guarantee 5 per cent. of the bonds, and will pay back the amount in gross freight receipts over the extension, handing over 70 per cent. until the loan is wiped off. The power line from Sandy Falls has been completed and electricity can now be supplied to any of the properties desiring it. The Timmins McMartin and Dunlap syndicate is going to establish a townsite on the Campbell veteran claim adjoining the Hollinger. A certain portion will be retained for the homes of the employees and the remainder sold to the public. The syndicate will bring water from the Mattagami River for the mill and the town, and as the settlement will be on a sand plain, sanitation presents no great problem.

The damage done by the fire at the Hollinger will cause a delay in arriving at the producing stage of at least eight months. Everything was damaged almost beyond repair with the exception of the compressor, the two boilers, and a storehouse. So fierce was the blaze that the men, from the superintendent downward, lost nearly all their personal effects. Until the railroad is completed or the winter roads open, it will be almost impracticable to bring in the heavy mill machinery over the present road from South Porcupine, and the attempt will not be made. In the meantime the veins laid bare by the are being thoroughly sampled and a reconstruction of the p carefully mapped out. Instead of 40 stamps, at first pla before the fire, 60 will now be installed.

Excellent progress is being made with the 40-stamp mil the Dome. It is now announced that the stamps will be drop by the middle of October. The 12-drill compressor is now ning and furnishing all the power needed both for the struction of the mill and underground. Here two shafts being sunk in the big ore body 250 feet apart. They wil sunk at once to the 500-foot level and are both down to 125-foot already. The Dome also had to fight fire for the w of one day, but the force of 200 men was well organized nothing was lost.

In the vicinity of Pearl Lake excellent discoveries have made on the Pearl Lake Gold Mines, the Jupiter property der option to the Drummonds, and the Armstrong Booth. Pearl Lake has a large number of showings of visible gol small quartz stringers in the schist. On assay it has shown in some cases that the schist carries good values.

The Jupiter, which is on the same series of veins, has a spectacular surface showing in a quartz lead about five wide. Down the shaft, which is being sunk by contract, the free gold persists, and the assays are very encouraging. Drummonds, of Montreal, have an option on the control of stock, and the property is being vigorously worked. At one of the Jupiter veins has been traced and laid bare ac on to the Armstrong-Booth, and here both surface assays diamond drill cores are very encouraging. At the end

End of Steel early in June

Pearl Lake the Bewick Moreing and Company engineers h made their headquarters. Many of their 50 claims are be carefully trenched upon and sampled.

Sinking between a series of quartz stringers bearing gold on the surface, the Preston East Dome struck into a or five feet wide ore body at a depth of 40 feet. A si compressor is running and a small stamp mill is on the gro for use whenever it is required.

A good discovery has been made on the property of Scottish Ontario syndicate, in Whitney. A shaft was sunk a small vein and about twenty feet down the vein wide and became enriched.

Some spectacular samples from Bristol Township, west the Cripple Creek camp, have caused a stampede into that tion. It is stated that some months ago the original discov was made and is now under option to an American syndic at a long price. So far Cripple Creek, while yielding some markably good assays, has been able to show very little gold.

Several good discoveries have been made on the Swast camp in the last two or three weeks, and the competition claims is growing. West of the Swastika mine some six mi

eport of a big silver find precipitated a crazy stampede, othing but diabase has been discovered so far. The Swas- Company has definitely ordered its large plant, but will crease the size of its mill until further exploration work evealed adequate reserves of ore.

BRITISH COLUMBIA.

T Board of Conciliation and Investigation appointed to igate matters in connection with the failure of the West- oal Operators' Association and the officers of District No. 8, United Mine Workers of America, to agree as to terms and onditions under which the miners and other employees will eturn to work in the coal mines and at the coke ovens of berta and southeastern British Columbia, resumed its sit- ng on June 7th after having been in recess about a month. Litt progress toward a settlement of the several points in ispe between the operators and the representatives of the min s seemed to have been made by the middle of June. The Op tors' Association has lately been joined by the McGilli- ra Creek and Canada West Companies, both operating in A ta, the former near Coleman, and the latter at Taber.

A opos of this labour difficulty, Mines and Minerals, of Scr ton, Pennsylvania, published in its June number the fol- lowg, under the caption of "British Columbia Labour ro les." "At this writing the labour troubles in the North- wes are unsettled and operators are preparing for a period of leness. The railroads are contracting for coal in the Unid States. Large shipments will be made over the Great Lak into Canada. The Great Northern Railway Company is seeg to place contracts for coal in the States of the North- wes Under these circumstances it will not be long before the ope tors and miners settle their differences by arbitration." Unf tunately, though, this long-distance guess does not at pre nt seem likely to prove a correct one.

C iboo.—A press despatch from Barkerville, Cariboo, states tha a London syndicate, represented locally, has secured an opt n on the hydraulic placer gold claims held by the Gug- gen ims, and formerly the property of the Consolidated Car oo Hydraulic Gold Mining Company, of which Mr. John B. bson was manager. The property is situated at Bullion, in he vicinity of Quesnel Forks. When the Guggenheims bou t out the interests of the Consolidated Cariboo Company the planned to make ample provision for a much enlarged sup y of water for gravel-washing. Construction work was car d on until a comparatively large sum of money—stated t about $200,000—had been expended with the object of bring- ng n much more water, when operations were stopped, and afterwards the big hydraulicking plant and a large quantity of mat ial on the property were sold. Understanding that the hyd aulic leases had been forfeited, Mr. Hobson, who still has onfidence that with sufficient water available the enterprise can e made a profitable one, made application for some of the ground and commenced work on it with the small quantity of wat r then obtainable. The Guggenheims, however, paid up the rrears of rent, etc., due to the Provincial Government, and suc ssfully made application to the court for an injunction against Mr. Hobson's working the property. Since then it has bee idle, and Mr. Hobson has turned his attention to another hyd aulic property in the same neighbourhood.

Sheep Creek.—The Hon. Thomas Taylor, Minister of Public Wo ks for British Columbia, recently visited Sheep Creek camp, in he Nelson mining division. The journey was made from Nel on to Salmo by train, and thence to the camp by auto sta , the run from Salmo to the first mine visited having oc- cup d an hour and a quarter. Upon his return the Minister sai when interviewed by a representative of the Nelson Daily Nes: "This is the first occasion for some years upon which I ve visited a mining camp such as Sheep Creek camp is, and it reminded me of the old-time boom days. As we sped alo the road to the camp we passed many teams conveying supplies to the mines, and we saw a large number of men in the hills and at the mines. I was told that there are at present at least 400 men in the camp. Sheep Creek camp is certainly making remarkable progress and seems destined to have a great future. It is a real pleasure to me to see the waggon road the Provincial Government has constructed being made so much use of. Obviously it is proving of great benefit to mine owners and prospectors."

Mining in Sheep Creek camp is being proceeded with actively. The owners of the Queen are developing that mine at greater depth than in the past. The Mother Lode, owned by Mr. John McMartin and associates, is being provided with a mill and other gold-saving facilities. The Nugget is to have a 20-stamp mill in place of the 4-stamp mill it has heretofore used. The Kootenay Belle will also be in a position before long to mill its ore. A majority interest in the Summit has been sold to Eastern men, and several other claims are being developed with encouraging results.

Kaslo.—A local syndicate has purchased from the Great Northern Railway Company the Kaslo & Slocan Railway, which was much damaged by forest firo last summer along its length from Sproules to McGuigan, thus depriving the Whitewater group, Lucky Jim, Rambler-Cariboo, and other mines on the divide between Kootenay and Slocan lakes of convenient transportation facilities. During the interval between last summer and the recent negotiations for the purchase of the K. & S. Railway, the Canadian Pacific Railway Company had been urged to construct a spur from its Sandon-Nakusp branch at Three Forks up Seaton Creek towards the summit of the divide, so that ore might be shipped in considerable quantity from the Rambler-Cariboo and Lucky Jim mines, both of which had been practically deprived of income by the destruction of the railway that had long transported their ores to Kaslo for shipment thence to the smeltery. It is understood that arrangements had been entered into and the C.P.R. was arranging preliminaries, so that construction could be pushed during the summer and autumn. Now the new owners of the K. & S. are appealing to the C.P.R. Company to hold its hand aud not proceed with the construction of the promised spur, for if this be built it will take away the chief freight traffic the K. & S. would otherwise obtain, and so prevent the operation of the line under its new owners. It is stated to be probable that the C.P.R. will postpone construction of the extension from Three Forks, and thus leave this small field for the support of the K. & S. Railway, upon the continuous working of which Kaslo will have to depend for much of its general trade and commercial support.

Boundary.—As the first half of the year draws to its close it is regarded as probable the total output of ore for this period will reach an aggregate of about 750,000 tons, and this notwithstanding that the Granby Company's mines will have missed nearly a month's output, and that the Consolidated M. & S. Company has not latterly shipped any considerable quantity of ore from its district mines.

The British Columbia Copper Company continues to draw its chief supply of ore from the Mother Lode and Rawhide mines, with much smaller quantities from the Wellington and Athelstan mines, both in British Columbia, and the Lone Star and Napoleon mines, situated just south of the international boundary line. This company is about to commence development work at the McKinley mine, in Franklin camp, about 50 miles above Grand Forks. The Geological Survey has a field party at work in Franklin camp, obtaining data for the preparation of a map of this part of the Boundary district.

Provincial newspapers have lately stated that the British Columbia Copper Company's dividend, payable on June 1, was at the rate of 2½ per cent. and totalled $62,875. The Engineering and Mining Journal shows the dividend distribution to have been at the rate of 12½ cents per share on the company's

591,709 issued shares, making a total for this dividend of $73,963.63. Dividends previously paid by this company were: one at the rate of 40 cents per share in September, 1907, on 503,000 issued shares, total $201,200, and one of 12½ cents per share on March 1, 1911, on 591,709 shares, total $73,963.63. These three dividends give a total of $349,127.26. It may be explained that during its fiscal year, ended November 30, 1909, the company issued 88,709 shares of its treasury stock in part payment for the controlling interest it then acquired in the New Dominion Copper Company.

Coast.—Announcement has been made of the intention of the Vancouver company which last year acquired the Ikeda mine, on Moresby Island of the Queen Charlotte group, to do more development work on this property. Prospecting the coal measures occurring on Graham Island, of the same group, is in progress on several properties.

Coal mining on Vancouver Island is on a gradually increasing scale. Both the larger companies, namely, the Canadian Collieries (Dunsmuir), Limited, and the Western Fuel Company, are extending their development operations, with the object of opening new coal-producing areas in their respective large holdings of coal lands.

Copper mining in the southern part of the Coast district is being continued on Texada Island—at the Cornell mine, by the Tyee Copper Company, and at the Marble Bay mine, by the Tacoma Steel Company—and at the Britannia Mining & Smelting Company's Britannia mines, on Howe Sound. The last-mentioned company is showing persistent enterprise in continuing the extensive exploration of its large group of mineral claims. While no official information has been made public, it is freely reported that results lately have been encouraging.

COMPANY NOTES

DOMINION COAL COMPANY, LIMITED.

Report of the Board of Directors.

Presented to the shareholders at the annual meeting on 19th May, 1911.

Your directors submit herewith a statement of the affairs of the company as at 31st March, 1911, and of the earnings for the fifteen months then closed.

Change in Financial Year—In order that the annual meetings of the shareholders of the Dominion Steel Corporation, Limited, and of its subsidiary companies may be held at the same time, your directors have changed the financial year so that it ends on 31st March instead of 31st December. The report now presented covers the period from 1st January, 1910, to 31st March, 1911.

Business of the Year—The strike which was in existence at the date of our last annual meeting was abandoned by those concerned at the end of April, 1910, and as soon as possible thereafter full operations were resumed at the collieries.

The output was as follows:

For the 12 months ending 31st December, 1910, 3,526,754 tons.

For the 15 months ending 31st March, 1911, 4,412,639 tons.

The output in the preceding year, January to December, 1909, was 2,734,774 tons, and in 1908 3,555,068 tons.

Earnings—In considering the statement of earnings your directors would remind you that the period covered by the report includes four months in which the strike existed, that even when ended it was many months before the disorganization which it caused ceased to be felt, and that an extra winter period—December, 1910, to March, 1911, is included, during which earnings are necessarily small. The net result, under these conditions, is in your directors' opinion reasonably satisfactory.

Property and Plant—The capital expenditure on the company's property during the 15 months amounted to $784,366.92, chiefly for work on the new collieries in the Lingan district, and for additional railway equipment. It has been thought well to transfer $500,000 from profit and loss account as a general appropriation in reduction of the property account.

The company's plant is in very good condition, and your directors look for an increased production in the current financial year.

Cumberland Railway and Coal Company—During the year the Dominion Steel Corporation, Limited, came under agreement to purchase the entire capital stock of the Cumberland Railway and Coal Company, and an agreement for the lease of its property to this company was entered into, under which its collieries are now being operated as collieries of the Dominion Coal Company, Limited. Their output is not included in the tonnage reported above.

The Cumberland Company owns large and valuable areas in Cumberland County and in Cape Breton; it has collieries at Springhill, a well-equipped standard gauge railway from Springhill Junction to Parrsboro, 32 miles in length, a large area of timber lands, and other property.

A strike has been in existence amongst its employees for some time, but your directors hope that the reasonable attitude of the executive, coupled with the refusal of your directors to recognize in Cape Breton the United Mine Workers Association of America, of which it is sought to enforce recognition in Springhill, will shortly lead the men to take more reasonable views.

Changes in the Board—Mr. James Crathern, who was a director of the company for some years, died in June last, much regretted by his colleagues on the board and by his many friends elsewhere. The vacancy caused by his death was not filled. The vacancies caused by the death of the Honourable L. J. Forget and Mr. H. F. Dimock, elsewhere referred to, were filled by the election of the Honourable Senator Dandurand and Sir William Mackenzie.

Staff—Your directors again desire to record their high appreciation of the services rendered to the company by its officers and employees.

On behalf of the Board of Directors,

J. H. PLUMMER, President.

Montreal, 9th May, 1911.

R. GORDON, Comptroller.

JUPITER MINES.

The reorganized board of directors of Jupiter Mines, Limited, is as follows: H. J. Hamilton, A. W. McDougald, C. A. Masten, K.C., John Wood, and James Pearson, the latter selected by minority interests to succeed Major Murray and Mr. O'Kelly. All details in connection with the completion of the Drummond Syndicate purchase of 900,000 shares of treasury stock have been sanctioned by the shareholders.

BUFFALO MINES ANNUAL REPORT.

The annual report of the Buffalo mines will show a production of 1,500,000 ounces, while the ore reserves are still maintained at practically what they were last year, 4,000,000 ounces. The mill treated 41,000 tons of rock during the year, and produced 1,250,000 ounces of silver, giving an average of about thirty ounces per ton milled. The company has paid a regular 8 per cent. per quarter through the year, and has now distributed among shareholders considerably over a hundred per cent. on capitalization.

BUFFALO MINES DIVIDEND.

Buffalo Mines Company has declared a regular quarterly dividend of 5 per cent. and 3 per cent. extra, the former payable July 1, and the latter August 15.

CROWN RESERVE DIVIDEND.

Crown Reserve declared a dividend of 2 per cent., with the usual bonus of 3 per cent., payable July 15 to shareholders of record June 30.

DIVIDEND NUMBER ONE.

Notice is given that a dividend of one per cent. upon the capital stock of the Dominion Steel Corporation, Limited, has been declared, payable on and after 3rd July, 1911, to shareholders of record at the close of business on Tuesday, 20th June instant.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt Camp for the week ending June 16, and those from Jan. 1, 1911, to date:

	June 16, Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger	.....	55,200
Bailey	.....	40,000
Barber	.....	6,000
Beaver	.....	716,708
Buffalo	61,690	1,349,700
Chambers-Ferland	64,000	639,000
City of Cobalt	.....	493,780
Cobalt Lake	249,840	2,055,090
Cobalt Townsite	.....	480,700

Colonial	46,000	88,000
Coniagas	63,160	1,936,680
Crown Reserve	.....	1,208,220
Hargraves	60,000	161,100
Hudson Bay	64,210	502,660
Kerr Lake	60,010	1,322,040
King Edward	.....	40,000
La Rose	85,460	2,850,330
McKinley-Darr-Sav.	121,040	2,808,330
Nipissing	245,350	2,960,260
O'Brien	65,250	673,040
Peterson Lake (Little Nip.)	.....	58,430
Provincial	.....	40,510
Right of Way	60,100	579,560
Silver Cliff	.....	106,680
Standard	.....	102,813
Temiskaming	85,550	860,852
Trethewey	.....	672,380
Wettlaufer	.....	117,232

The shipments for the week were 1,328,660 pounds, or 664 tons.

The shipments from Jan. 1 to June 16 were 22,825,295 lbs.

NIPISSING IN MAY.

During the month of May the Nipissing Mines mined ore of an estimated net value of $221,584, and shipped ore of an estimated net value of $219,898, according to the report of Manager Watson to the directors.

In part he says: "With the return of satisfactory air pressure operations underground were resumed at all points and the production was again normal."

B. C. ORE SHIPMENTS.

The weekly mine and smelter returns record the second week of the Granby shut-down. Both mine and smelter are expected to resume the latter end of this week.

The following are the returns of the ore production and movement for the week ending June 10th, and for the year to date:—

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing w a large part of Canada, with many local areas and special subje

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired wil sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definately the precise area c cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for w it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mi Institute, etc.

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners. Chilled Wheels and Castings of all descriptions.

THE
SUDBURY CONSTRUCTION & MACHINERY CO.
LIMITED
SUDBURY :: ONTARIO

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of the height of land, where important mineralized belts are known to exist.

Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, MONTREAL, for the determination, assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

Cyanide 98/99 per cent.

Cyanide of Sodium 128/130 per cent.

Cyanide of Sodium 120 per cent. In Brick form.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

Address—Mr. Ch. CHAUTEN,
123 Rue Lamark, PARIS.

The Best New Books for Mining Engineers

Just Issued

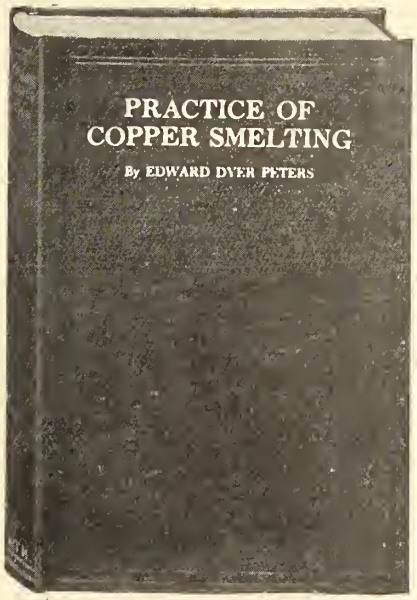
Practice of Copper Smelting

By EDWARD DYER PETERS,
Professor of Metallurgy, Harvard University.

3 pages, 6x9, illustrated $5.00 (21s.) net, postpaid.

This new work is devoted to the modern, actual methods of Copper Smelting with just enough of the principles to give a clear picture of the reasons for each stage of the operation.

It is the fruit of the author's wide experience and extensive research coupled with the information offered by the principal American Smelting Companies.



Dr. Peter's book presents many important matters which cannot be found elsewhere. It tells of the use of Oil as fuel in reverberatory smelting; pulverized coal in reverberatories; modern converter practice with actual results and costs; the basic lined converter with plans; "Fines"; "Slags"; etc.

It is a companion volume to "Principles of Copper Smelting"

Principles of Copper Smelting

612 pages, 6x9, $5.00 (21s.) net, postpaid.

Modern Copper Smelting

600 pages, 6x9, $5.00 (21s.) net, postpaid.

Mining Books

Underground Surveying

Corrected Edition.

By LOYAL W. TRUMBULL, E.M.

2 pages, 6x9, illustrated, $3.00 (12s. 6d.) net, postpaid.

Compressed Air

By ELMO G. HARRIS, C.E.

Professor of Civil Engineering, University of Missouri School of Mines.

16 pages, 6x9, illustrated, $1.50 (6s. 6d.) net, postpaid.

Timbering and Mining

By W. H. STORMS.

0 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

Principles of Mining

By H. C. HOOVER.

0 pages, 6x9, illustrated, $2.50 (10s. 6d.) net, postpaid.

The Cost of Mining

By JAMES RALPH FINLAY.

415 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

Tables for The Determination of Minerals

Rock Drills

Design, Construction, Use

By EUSTACE M. WESTON

367 pages, 6x9, illustrations, $4.00 (17s.) net, postpaid.

Describes the leading modern makes of English, Australian and American drills. It assists in choosing machines most suited to particular needs, and using them with the greatest efficiency.

Practical Shaft Sinking

By FRANCIS DONALDSON, M E

143 pages, 6x9, illustrated, $2.00 (8s. 6d.) net, postpaid.

The author presents an immense amount of good material in a small space. It is a *timely* volume for mining engineers.

Principles of Metallurgy

By CHARLES H. FULTON,
President and Professor of Metallurgy, South Dakota School of Mines.

536 pages, 6x9, illustrated, $5.00 (21s.) net, postpaid.

The standard work on this subject. The treatment of the subject is modern. The author presents new ideas, and the style is clear and terse.

Books on Metallurgy

Clennell's Cyanide Handbook

By J. E. CLENNELL.

526 pages, 6x9, illustrated, $5.00 (21s) net, postpaid.

Ore Dressing

By ROBERT H. RICHARDS,
Professor of Mining and Metallurgy, Massachusetts Institute of Technology.

Four volumes, 2,000 pages, 6x9, illustrated, per set, $20.00 (£4 4s.) per volume, $5.00 (21s.) net, postpaid.

Elementary Crystallography

By W. S. BAYLEY, PH.D.,
Associate Professor of Mineralogy and Economic Geology, University of Illinois.

236 pages, 6x9, 300 illustrations, $2 00 (8s. 6d.) net, postpaid.

Metallurgy of Lead

and the Desilverization of Base Bullion

By H. O. HOFMAN.

600 pages, 6x9, illustrated, $6.00 (25s.) net, postpaid.

Metallurgical Calculations

By JOS. W. RICHARDS.

Three volumes, each volume over 200 pages, 6x9, $2.00 (8s. 6d.) net, postpaid per volume.

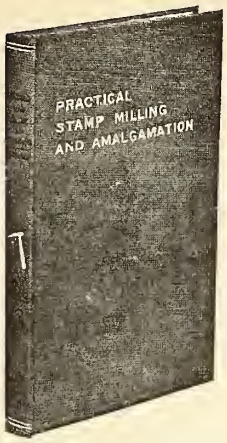
FOR THE MILLMAN

Practical Stamp Milling and Amalgamation



By H. W. MacFARREN

166 PAGES INDEXED

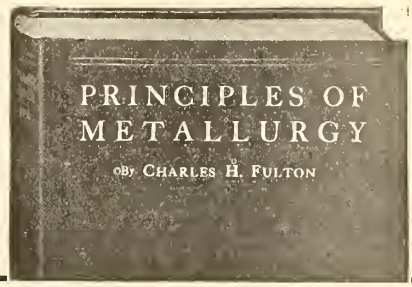
$2 POSTPAID

Written primarily for the millman himself, this book will prove of value to all those having to do with the milling of gold ores. Gives details needed in everyday work. The stamp mill, its location, and design; the mortar, die, shoes, tappet, and cam; adjustment of height, order of drop, feeder, and screens; water supply and power; principles of amalgamation and treatment of plates; retorting; loss of gold, mill tests, and mill management; all these are treated in an illuminating manner by one who has himself solved the problems.

Book Department

CANADIAN MINING JOURNAL

TORONTO



THE standard treatise in English on general metallurgy. It is of the highest value and greatest practical use to every metallurgist. The sections on Alloys, Measurements of High Temperatures, Slags and Mattes are very important.

The author is President and Professor of Metallurgy, at the South Dakota School of Mines.

The Main Chapter Headings Are:

I.—The Metals and Metallurgy from the Historic Point of View. II.—Physical Mixtures and Thermal Analysis. III.—Physical Properties of Metals. IV.—Alloys. V.—The Physical Properties of Alloys. VI.—The Measurement of High Temperature. VII.—Typical Metallurgical Operations. VIII.—Slags. IX.—Matte, Bullion and Speiss. X.—Refractory Material for Furnaces. XI.—Fuels. XII.—Combustion. XIII.—The Production and Heating of Blast Furnaces. XIV.—An Example Illustrating the Physics and Chemistry of a Melting Operation. The Blast Furnace for Copper.

536 pages, 6x9, 188 illustrations, $5.00 (21s) net, postpaid.

Book Department

CANADIAN MINING JOURNAL, TORONTO

BRITISH COLUMBIA

The Mineral Province of Canada

h produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; o a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 s Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has n even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the minion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by own Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

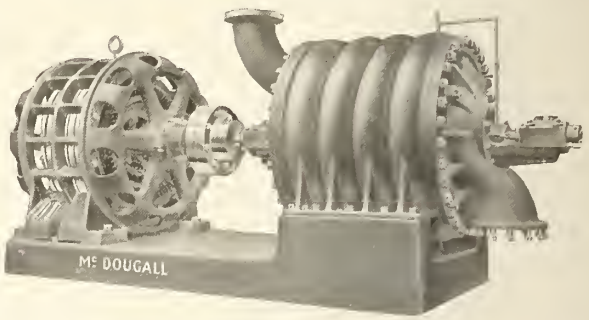
Turbine Pumps
FOR
Mining Work



An interesting application of these turbine pumps is made at the smelting works of the Mond Nickel Co., Limited, Victoria Mine, Ont. The furnaces flow continually into settlers and the slag overflow is granulated by a high pressure stream of water, through a 1½" diameter nozzle, which carries the slag in 5" diameter manganese steel pipes to the dump about 500 ft. from the furnaces. Two 8" four stage pumps are used, each having a capacity of 1250 Imperial gallons per minute against a head of 500 ft. Each of them is driven by a 300 H.P. motor at 1,200 r.p.m. The granulating of the slag is very satisfactory.

When necessary the impellers and chambers of mining pumps will be built of bronze to resist the corroding effect of acids.

Pumping slag. Mond Nickel Co., Limited.

Renold Patent Silent Chains

What Users Think

MONTREAL, Feb. 8, 1909.

Messrs. Jones & Glassco, Montreal.

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your enquiry of Jan. 30th, I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.

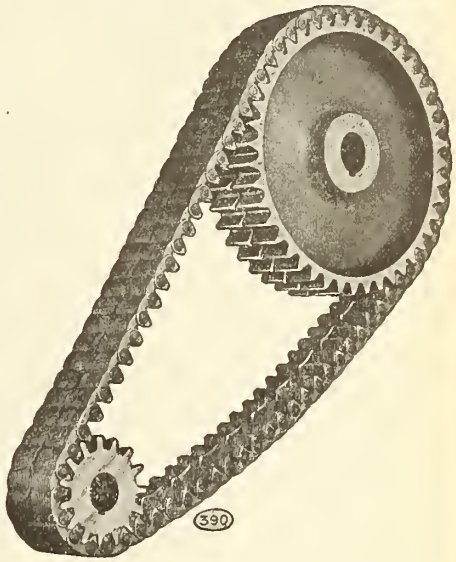
Our first drive was installed to replace a 12 in. belt which was giving us trouble on account of short centres; this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing; this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears and this has been so successful that we are now installing two more similar drives.

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drive in operation.

—The above comes from one of the largest manufacturers in Montreal and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.



Write for particulars.

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

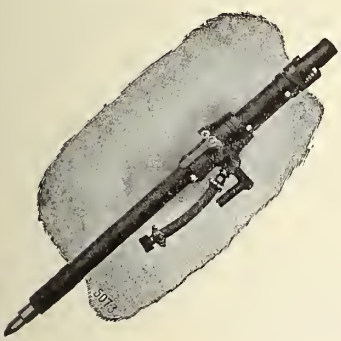
Montreal, Toronto, Winnipeg, Vancouver, St. John, N.B. Halifax, N.S.

TELESCOPE FEED

HAMMER DRILLS



Hammer Drill manufacturing really resolves itself into the problem of building light rock drills for economical mining purposes.

The Hammer Drill that most nearly approaches rock drill construction, that will stand up to rock drill service and not deteriorate under rock drill treatment is the best hammer drill to buy.

This Company has combined the best principles of the reciprocating piston drill with the most advanced ideas in hammer drill construction and have succeeded in producing in the "BC-11" Telescope Feed Hammer Drill a tool of unprecedented efficiency and reliability.

The "BC-11" means sustained economy to its users, lower mining costs and less trouble. It's the drill that stays underground.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale	9.15 p.m.	Leave West Toronto	9.30 p.m.
Arrive North Toronto	9.40 p.m.	Leave North Toronto	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

MINING AND THE COST OF LIVING.

Of late years the scales have been removed from the eyes of the consumer. Publicists, through our most effective magazines, have made it plentifully plain that all of us pay more than we should for the neeessaries of life and industry. The wide movement of reform that is spreading over America is manifested chiefly in the public exposure of the intricate iniquities of trusts, and in official investigations that sometimes bring results and sometimes do not. But reform, vaguely perhaps, and only rarely crystallized into definitive acts, is nevertheless pervading the atmosphere, not only in Americea but pretty well over the civilized world.

From South Africea, where the mining and farming communities feel most keenly the unbalanced ineidenee of taxation, there comes word of evidenee given before the Industries and Commerce Commission. The witnesses examined were representatives of the consumers' organization. Let us glance for a moment at their asseverations.

Whilst the peculiar and pressing need of South Africa is a larger population of whites, yet the same injurious fiscal and industrial conditions obtain there as in Canada. As illustration, here is an exeerpt from evidence taken: "No tariff can increase the total amount of work for white men in South Africa, but it may, and probably will, diminish it. . . The miner and the farmer have to earry the burden of protection. They subsidize protected industries, which in many cases means subsidizing the Kaffir and the coloured man who do not even purchase the articles they produce." The point is developed that only when the white man is enabled to live in decency and comfort at the lowest possible cost will he attain his fullest effectiveness.

Amongst the positive suggestions made, several bear upon bounties and subsidies. It is urged that customs duties be levied for revenue purposes only, and apply mainly to luxuries; that railways be run at eost and deficits of branch lines be paid out of general revenue; that coal, raw materials, and food supplies be carried at minimum rates; that harbour deficits be met out of general revenue; and that temporary bounties be granted to industries dependent upon raw material, provided there is reasonable ground for believing that they can shortly survive without the bounties. In short, a general downward revision of duties and railway rates is requested, along with a judicious trying-out of a temporary system of bounties. One strong point made refers to the fact that the local Johannes-

burg manufacturer is amply protected by the cost of laying down foreign goods in that city. He needs no tariff wall. It is shown also that the man with a family to support bears a burden of taxation out of all proportion to that borne by the bachelor. "It would be difficult," continues the evidence, "to conceive a more foolish and iniquitous system of taxation for a new country in need of white population."

The parallel between Canada and South Africa holds in a general sense. In detail, the circumstances of the two Dominions are widely divergent. The mining industry of the Rand is highly organized. Costs are so closely controlled that the immediate effect of extraordinary charges can be readily traced. The large gold mines are placed upon an industrial basis. Reserves are estimated more exactly than is possible in less favoured regions, and expenditure is carefully governed by engineering factors. Briefly, South Africa is pre-eminently a mining region. In agriculture and in manufacturing it has made but slight progress.

In contrast, Canada's chief industry is agriculture. But Canada also has large lumbering, mining, manufacturing, and fishing interests. Directly and indirectly Canadian manufacturers are enormously subsidized. Tariffs, bonuses, special subsidies, and a score of equally expensive devices aid the manufacturer. The consumer pays for all. Naturally the agriculturist, the lumberman, and the miner are bled.

The Johannesburg Daily Mail quotes from Mr. J. J. Harpell's book, "Canadian National Economy," a paragraph tracing the decline of Canada's gold output to the increased cost of living. Whilst we admit freely that in a country like South Africa, where gold mining has attained a degree of solidarity, any addition to living expenses will react at once upon the industry, we contend that Canadian gold mining has never reached the stage where the cost of living has become a serious factor. The impression that the Yukon, for instance, would still be producing on its old scale had it not been for inflated costs is entirely beside the point. Every new Canadian mining camp goes through a period of high prices; and each camp must ultimately be worked by large corporations on its own merits.

We do not deny that the cost of living is a problem in mining as in all other activities. But it does not become a problem in precious metal mining until certain other elements have had full play. The Yukon is thriving and probably will continue to thrive. Deserted gold mines are being re-opened in Nova Scotia and Ontario. If the cost of living was prohibitory ten years ago it is certainly much more so now. Yet never has there been more activity than at present. The volume of output is principally a function of the generosity of nature.

THE FLOODING OF THE PORT HOOD COLLIERY

From the accounts available at the time of writing there seems to be no doubt that the Port Hood Colliery has been inundated by water from the oce entering through a break in the submarine cov Sufficient particulars are, however, not as yet ava able to enable an opinion to be formed as to the cau of the inundation and the possibility of the cau having been preventable.

The Port Hood colliery has had many vicissitud and it has probably never made any money for owners. The first attempt to mine coal at Port Ho was made in 1865 by the Cape Breton Mining Co pany, who drove a slope from the crop of the six f seam; but operations were suspended in 1867.

The Port Hood mine at the present time has a ma slope extending 2,800 feet from the surface at angle of 27 degrees. The company operating is t Port Hood and Richmond Coal & Railway Compa and for some time past the bondholders have been possession, and have made a very determined effort make the mine pay. A new compressor was recent installed and coal-cutting machines were put to wo underground. One difficulty of coal mining on t Inverness shore is the lack of suitable shipping por and the long drift-ice season, requiring the banki of large quantities of coal in the winter, which in turn means the tying up of large sums of capital. D ing the summer the men worked irregularly, pref ring to find employment on a breakwater which t Government have been constructing for many ye to preserve the harbour of Port Hood. The unfor nate flooding of the mine will prove a ruinous blow the town of Port Hood, and is greatly to be regrett

The Inverness coalfield seems to have been parti larly unfortunate, both in its financial aspects and natural features. There can be little doubt that t detached basins of Chimney Corner, Broad Cove, M bou, and Port Hood are all remnants of one gr coalfield, which has been split up by folds of t strata and afterwards denuded, until nothing is l but the bare tips of the coal basins at the shore. So of the seams have without doubt disappeared un the waters of the Atlantic; others are visible at l tide only, and all the time the sea is encroaching what is left. In 1871 Mr. Richard Brown express the opinion that "immediate steps should be taken the Government to ascertain the exact situation a economic value of every seam of coal in Inverne because, owing to the rapid wearing away of the cli on a coast exposed to the heavy surf of the Gulf d ing the prevalent northwest winds, and to the co bined action of severe frosts and rapid thaws, vestiges of these valuable coal-seams will soon be tirely obliterated. In proof of this view it need on be stated that Seal Island, composed of carbonifer strata, which, beyond all doubt, was once connect with the mainland, is now separated from it by channel two miles in width, the intervening land h ing been entirely swept away by the waves. It evident, therefore, that a belt of coast, at least t

s wide, has disappeared, effacing the outcrops of y valuable seams of coal. If this process be re- ed to the extent of only one mile more, it is lly evident that all the outcrops now visible will e washed away, leaving 'not a wreck behind.' If ect plans are made, showing the position of every sea, at a future time, when all traces of them have dis peared, they may be reached by cross-cuts driven fro the bottom of shafts sunk upon the adjacent she e, and worked under the sea."

is comparatively recently that the Mabou mine, wh h lies some six miles to the northward of Port Hoo d, was flooded from the sea, and it is improbable tha this mine will be re-opened. The Government of Nova Scotia can hardly err in taking whatever steps the deem necessary to prevent the flooding of the ac- essible portions of these submarine areas, because it ma well be that such occurrences may render it im- po ible ever to mine the coal-seams that lie further ou to sea.

oubtless, the unfortunate accident at Port Hood w i add something to our knowledge of the mining of su marine coal, and some useful deductions may be ma e for future guidance when more definite infor- ma ion is available. It may not be generally known tha by far the greater portion of Nova Scotia's coal sea s are submarine, and it is difficult to exaggerate the importance of their conservation, since they con- stitute the main source of the Provincial revenue. They also constitute the best guarantee for the future industrial development of the Maritime Provinces and eastern Canada in general.

SALARIES.

ot once, but many times, have we urged upon the po ers that be the policy of paying higher salaries to th officers of the Federal Department of Mines.

n the last annual Summary Report, Mr. R. W. Br ck, Director of the Geological Survey, puts the ca e strongly. In part, he writes thus: "The salaries pa l to technical officers are too low. . . . More wi have to be done if the Survey is to attract and re in the type of man that is needed to secure good re lts. . . . The first requirement is the man; the fa lities for work are of only secondary importance."

Mr. Brock then proceeds to show that the system of gradual promotion is inimical to the Survey's best interests. The lowest salaries paid to technical offi- ers are attractive only to young graduates who have a reputation to make. Such men are engaged by cor- porations at the very time that their services are be- coming of value to the Survey. The loss to the Sur- vey, which is forced to begin all over again with raw material, is serious.

Another problem presents itself when experienced geologists are attached to the staff. These men can be held only by giving them the highest salaries paid by the Survey. Manifestly this is unfair to the older officers whose salaries increase slowly from year to year, and who have not yet reached the highest division.

Mr. Brock does not suggest any alternative for the present system, the imperfections of which need no demonstration. He confines himself to asserting that larger salaries are needed if the Survey is to retain its dignity and its usefulness.

We are inclined to believe that the solution of the difficulty lies in the hands of the Director, in part at least. Naturally he will be helpless without larger support from the Government. But there are matters of internal economy that call for immediate change. For instance it is a patent absurdity to apply to the Survey the same graduated classification of officers as is applied to clerical departments of the civil service. The Survey officers are essentially technical. If classification be necessary at all, it should be as simple as possible. Merit and special qualifications should count more, and long service less.

Incidentally, the anomalous and unseemly "time-book" should be consigned to the scrap-basket. In view of the fact that the Survey staff is composed of reputable professional men, and is not a miscellaneous assortment of irresponsible clerks, the idea of forcing each officer to record his goings and comings is futile in the extreme.

It seems but fair to say that the Survey's claims will be listened to with more favour as soon as it has been placed upon a professional and not a clerical basis.

FAME.

What is fame? The answer is easy. A capable press agent can bring you a surfeit of fame — if only you point a cheque-book at him. And no one has been luckier in his press agent than Mr. John Hays Hammond, "Special Representative of the President of the United States of America" at the Coronation.

In an anonymous appreciation of Mr. Hammond that was published in the London Daily Mail lately, it is stated, metaphorically and hyperbolically, of course, that Mr. Hammond "can smell a gold mine a thousand miles away." There follows mention of the passionate yearning of the Czar of all the Russias to meet the man who could exercise, with so much benefit to his nation, his olfactory upon undiscovered mineral riches.

But, as the effusive scribe points out, Mr. Hammond has forsworn mining and is to devote the remainder of his time and energy, not to mention his acute sense of smell, to the cause of international peace. So eloquent is the admiring agent that a brooding feeling of security immediately descends upon us.

* * * *

What it costs in mere money to reach the heights that Mr. Hammond has reached, we can only guess. But there remains no doubt that he is famous and will remain famous. He stands unique, alone, the man with

the largest salary in the world, the man who has capitalized his proboscis from the Rand to Mexico, and from Siberia to Cobalt, where lies a mine called Nipissing.

MILLING IN COBALT.

That there is excellent milling being carried on in Cobalt is indicated by Mr. A. P. Globe's paper on another page. Mr. Globe is mill superintendent of the McKinley-Darragh. His knowledge is first-hand, and what he writes is keenly interesting.

An extraction of more than 90 per cent. on ore such as is put through the McKinley-Darragh mill is creditable indeed. The extraction of silver from a 43-ounce ore at the McKinley-Darragh is 90.55 per cent. The tailings contain only 4.1 ounces per ton. Costs, also, are kept low. The mill is equipped to treat 60 tons of ore per 24 hours. The milling cost per ton of ore milled is $1.30. The cost per ounce of silver recovered is three cents.

We note with approval that steps have been taken to install a hand-picking section, with the object of reducing the value of the ore that goes to the stamps.

In the swirl of other mining excitements the steady development of Cobalt has been lost to view. In the staid, progressive Cobalt of to-day it is hard to recognize any trace of the blustering mining camp of four years ago. But nothing is more worth following than the ever growing efficiency of a mining camp that has cut its eye-teeth, and is in the hands of competent technical men. Whilst our metaphors may be mixed, we wish to draw attention to the fact that Cobalt has reason to be proud of her mining and milling practice.

THE INTERNATIONAL GEOLOGICAL CONGRESS

Coal is to be the chief topic of discussion at the twelfth session of the International Geological Congress to be held in Toronto next summer. The Eleventh Congress discussed the iron ore resources of the world, and published the results in monumental volumes. Logical sequence suggests that coal be the next subject of enquiry.

Already there has been distributed a circular outlining the campaign that is under way. Concise reports are being obtained from all mining countries touching both worked and unworked deposits. Actual, probable, and possible reserves are to be estimated, and complete forms are provided to assist in classifying scientifically each particular fuel and in determining its commercial value.

It is most urgently requested that each and every mining official do his best to aid in this world-wide stock-taking. The information thus gained will do much to forward the saner use of our most important mineral commodity.

EDITORIAL NOTES.

French capitalists are putting money into Newfoundland oil lands. Submarine claims between Pierson's Pond and St. Paul's Bay have been taken up.

In the volume on Porcupine published by the CANADIAN MINING JOURNAL, acknowledgment was omitted of the courtesy of Mr. A. C. Goudie in supplying tracings of the township maps.

The CANADIAN MINING JOURNAL is always anxious to receive notices of the movements of mining engineers. Brief items will be welcomed. It is good business for engineers to keep the mining public posted as to changes of address and absences from headquarters.

The representatives of the coal miners' unions of New Zealand have been requested by the British Admiralty to undertake to supply the navy at any time required, whether a strike exists or not. The reply of the unions was indefinite. They refused to bind themselves, but agreed to give due consideration to specific applications.

During the calendar year 1910, the Buffalo mine milled 41,484 tons of ore, averaging 36.07 ounces silver, a total of 1,496,255 ounces. The mill recovery was 80.07 per cent. The cyanide plant treated 11,[illegible] tons of slime from the mill, containing 13.06 ounces of silver per ton, or 152,783 ounces in all. The recovery here was 103,321 ounces, or 67.62 per cent. The total recovery by mill and cyanide was 1,301,396 ounces, or 86.98 per cent.

The extraordinary altruism of the larger breed of capitalist was never better demonstrated than by a recent utterance of Mr. Daniel Guggenheim. On leaving New York, Mr. Guggenheim delivered himself of a remarkable statement in which he expressed the fear that copper prices may soon become abnormally high. He dreads a "runaway price," and urges an organized community of copper interests so that prices may be kept at a decently low level. To Mr. Guggenheim we award the prize!

The Rev. Dr. Gordon ("Ralph Connor"), chairman of the Board of Conciliation that is attempting to patch up the dispute between operators and employees in southern Alberta and Crow's Nest Pass, showed singularly little discernment in his request that both sides send in a statement of their grievances and of concessions that they were willing to make. It is the chairman's business to collect, sift, and weigh the evidence. Then it is his duty to recommend such measures as he sees fit. Dr. Gordon's attitude is weak and puerile.

Personal and General

Mr. G. C. Bateman is at Elk Lake City.

Mr. Kirby Thomas, 20 Broad Street, New York, was in Toronto on June 28.

Mr. J. B. Tyrrell has returned from the Swastika mining region.

Mr. W. F. Ferrier, mining engineer, Lumsden Building, Toronto, has returned to town.

Mr. H. W. Hardinge, 50 Church Street, New York, has returned from a professional visit through western Ontario in the interest of New York clients.

Mr. Kirby Thomas, of New York, is in the Sudbury region.

Mr. A. E. Barlow has gone north to Cobalt and Porcupine.

Mr. William McGinnis is in Cobalt.

Mr. M. J. Butler, general manager of the Dominion Coal Company, recently visited the company's Springhill collieries.

Mr. Robert R. Hedley, who is now technical adviser to a Vancouver organization named the Canadian Mining Operators, has been spending several weeks in Nelson mining division, West Kootenay, B. C., making enquiries with a view to the purchase of mining properties.

Mr. Norman Carmichael, formerly manager of mines in the vicinity of Nelson, B.C., and now general manager of the Arizona Copper Company, with headquarters at Clifton, Arizona, was in Victoria, B.C., towards the end of June.

Mr W. Yolen Williams, of Spokane, Wash., will spend several months in the Coast district of British Columbia making enquiries relative to copper mining and smelting, and obtaining other information for the Granby Consolidated M., S. & P. Company, Limited. He will make Vancouver his headquarters while on the coast.

Mr. A. J. McMillan, liquidator of the Le Roi Mining Company, has gone to London. It is understood that a sale of the Le Roi mine, at Rossland, B.C., has been arranged, subject to confirmation by those who were directors of the company when liquidation was decided upon.

Mr. Andrew G. Larson, who lately paid a visit to Toronto, New York, and other cities, has returned to Vancouver, B.C.

Mr. Frederick G. Coggin, of the Deister Concentrator Company, has been spending some time in Idaho and eastern Washington, introducing his company's machines.

Mr. Byron N. White, of Spokane, Wash., president of the company owning the Slocan Star group of mines, near Sandon, Slocan, B.C., has lately been in Whitehorse copper camp, southern Yukon, in connection with the proposed resumption of operations at the Pueblo mine there.

Mr. James McEvoy has gone to the upper Skeena district, British Columbia, to open coal measures on property owned by a Toronto syndicate.

Mr. Jay P. Graves, vice-president and general manager of the Granby Consolidated M., S. & P. Co., Ltd., has returned to Spokane, Wash., from attending an important meeting of the directors held in New York.

Mr. E. Jacobs, of Victoria, B.C., has been re-elected secretary of the Western Branch of the Canadian Mining Institute, for the ensuing year.

Mr. Chas. Camsell, of the Geological Survey of Canada, is to do some reeonnaissance work in the Steamboat Mountain district, British Columbia, during the summer and autumn.

Mr W. M. Brewer, of Victoria, B.C., has resigned as president and director of the Pacific Metals Company to accept the position of general manager of the Matanuska Gold Mines, Limited, owning a free-milling gold quartz property in the Matanuska district, near the head of Cook's Inlet, Alaska. Mr. Brewer left for the north at the beginning of July.

Mr. George Safford, for a long time business manager of the Mining Journal, London, England, has joined the staff of The Mining Magazine.

Dr. A. M. Campbell, who returned from London and Scotland about a month ago, is at present in Porcupine. Dr. Campbell's permanent address is 70 Gloucester Street, Ottawa.

Mr. James Ashworth, late general manager of the Crow's Nest Pass Coal Co., has established an offiee at 1109 Hornby Street, Vancouver, B.C. Mr. Ashworth has had long experience in all phases of coal mining. He is thoroughly familiar with mining in the Canadian west.

Mr. Louis Reyersbach, managing director, and Mr. Hugh F. Marriott, consulting engineer of the Central Mining & Investment Corporation, of London, England, will visit this country in August. The corporation has recently taken over and consolidated with their own the interests of Messrs. Wernher, Beit & Company and Messrs. Eckstein & Company, the largest operators in Kimberley and the South African Rand. These gentlemen are making a tour of Canada and will visit the most interesting mining localities in this country in company with Mr. G. G. S. Lindsey, of Toronto, formerly president of the Crow's Nest Pass Coal Co. Arriving in New York on the 28th of July, they will proceed to New Brunswick and ultimately reach Vancouver, after which they will visit both the Skeena River and the Portland Canal. Mr. Marriott, it will be remembered, represented, with Mr. William Frecheville, the Institution of Mining & Metallurgy on the summer excursion of the Canadian Mining Institute in 1908.

Correspondence

DEEP DRILLING.

Chicago, July 3, 1911.

Gentlemen,—We note on page 403 of your July 1st issue, a summary of records of deep wells, including mention of one bored in 1905 near Johannesburg, South Africa, to a depth of 5,582 feet.

A few months after the hole referred to in your article was completed, John Skenke, an American drill contractor, using a Sullivan diamond prospecting core drill, class "P," completed a hole at a depth of 6,340 feet. A year or two ago, another American contractor, named William Gallagher, put down a hole on the Rand to a depth of about 6,600 feet.

The deepest diamond drill hole of which we have any record on this continent, was one bored in the summer of 1909, by Messrs. Cole & McDonald, of Virginia, Minnesota, near Republic, Michigan, with a Sullivan Class "D" diamond drill. This hole went to a depth of 3,265 feet.

Yours very truly,
"MINE AND QUARRY,"
S. B. KING, Editor.

Concentrating Methods at the McKinley-Darragh Mine, Cobalt, Ont

Written for the CANADIAN MINING JOURNAL by A. P. Globe, Mill Supt., McKinley-Darragh Mine.

Before going into the details of concentration at this mine, it should be pointed out that at nearly every mill in Cobalt the mill man has a different proposition in the concentration of Cobalt ores, which calls for some special treatment or permits of some step being omitted, or even permits some practice that would be prohibitive elsewhere

At one mine the values are carried in veins of very high grade ore, the wall-rock carrying very low or no values. Here a large percentage of values can be removed by hand picking or sorting plants. Under these conditions the ore going to the concentrator is reduced to from 10 to 20 ounces silver per ton. This enables the mill to make a high ratio of concentration and also a high grade of concentrates, but a lower extraction than where the veins are of a lower value and the values carried mainly in the wall-rock. The latter does not permit sorting to as great an extent before concentration as the former, therefore the grade of concentrates and ratio of concentration will be lower, but the percentage of extraction much higher, so it is hardly fair to compare such figures as ratio of concentration, average values of concentrates produced and per cent. of extraction.

It is not a matter of concentrating silver, but of the many grades of Cobalt ores.

In the following paper the writer has attempted to give correct information, to the best of his knowledge and belief, and it is to be understood that such figures as tonnage, value per ton, cost per ton and percentage of extraction, each depending one on the other, are estimated to a certain extent; that is, facilities are not provided to weigh every pound of ore and accurately sample mill feed as a customs plant must do. Figures may vary, although the law of averages will correct high and low points over a large tonnage and time.

The general formations milled at the McKinley-Darragh concentrator, are the Huronian slates and conglomerates with a certain amount of Keewatin. Generally the veins are small and split up, yet give a large amount of vein matter.

The metal of economic value in the veins and country rock is silver. It occurs in the form of leaf silver, argentite, ruby silver, dyscrasite, stomeyerite, freieslebenite, associated with smaltite, niccolite, glaucadot, calcite, and other sulphides and arsenides. The wall-rock slates carry a considerable quantity of sulphides and metallics, from a coating or paint of the former to nuggets of the latter. The many combinations formed by the various minerals and gangue give a specific gravity anywhere from 2.7 to 9.9, i.e., from calcite to dyscraseite.

Whereas the cyanide man's salvation often lies in the sliming of his ores, the reverse is the condition here. A certain amount of the values when once slimed will float away and no amount of mechanical concentration will save them, as has been found by returning the pulp over tables again and again under different conditions. As to the question of overcoming this difficulty, it will be seen from the flow sheet and tables that the sliming of values has been considerably reduced.

The accompanying flow sheet illustrates the flow through the mill:

The stamps are provided with slot screen .375-i x .187-inch aperture, .066-inch wire, 102 drops minute, 7-inch drop, level discharge, 90 per c water. This practice gives stamp duty of about 4 tons per 1,250-pound stamp, plus tonnage by-pas equals 146 tons per day of 24 hours for 30 stamps.

The following table gives distribution of values sizes in feed and discharge of stamps:

FEED.

	Mesh.	Per cent.	Assay
On	1¼-inch	11.	19 ounces.
On	1 -inch	14.	19 ounces.
On	¾-inch	21.	19 ounces.
On	½-inch	21.	19 ounces.
On	¼-inch	17.	19 ounces.
Through	¼-inch	16.	19 ounces.

DISCHARGE.

	Mesh.	Per cent.	Assay per ton.	Total oz. silv contained in 1 tons.
On	8	17 60	8.00	168.96
	10	4.30	8.24	42.52
	20	16.60	10.20	203.18

The run of mine is received in three separate bi which permits mine sampling of this spotty ore large lots.

On the first grizzly high grade is picked out a sacked, and after crushing to 3-inch the ore is c veyed to a shaking screen where high grade is ag picked out. After crushing to 1¼-inch, the ore is vated to a trommel 2½ x 6 mesh, where the unders is washed out and by-passed around the stamps this way 18 per cent. is removed. This is joined the hutch product from 6 Hartz jigs (the largest screen being 3-16-inch, round punch). This by-pass material and Hutch product is passed over an 8 x mesh screen, the over-size going to a Hartz jig. T under-size is separated, the sands to table feed, and t slimes are settled and shipped direct, without furth treatment. These slimes form about 1 per cent. the total ore and will average 200 ounces of silver p ton.

The over-size of 8-mesh from the stamp pulp, a tails from fine jig are re-ground in one 8-foot H dinge conical mill. This product, together with t stamp pulp under-size of 8-mesh, and about 4 tons sands from original wash (running about 70 ounc per ton) is classified for 10 sand tables and 4 Fr vanners. By coarse crushing only 19.38 per cent. slimes is made in the batteries, and the value of 1 per cent. of the battery pulp is reduced to 8 ounc before fine grinding. With the average stamp pu

running 19 ounces per ton the sands will run 22 ounces and the slimes 18 ounces per ton.

The tails from 6 Wilfley sand tables, which will run 5 ounces, are re-ground in one 5 x 20 tube mill and re-treated on 5 Deister tables. The tails from four sand tables treating the finer sands are retreated on old style Deister slimers. The tails from the 4 vanners are retreated on No. 3 Improved Deister slimers. The total tailings from the Deister floor pass over 28 canvas sheets before going to waste. Over the canvas tables the pulp is allowed to flow for about one hour, when the top is washed off and elevated to a Deister table, where it is cleaned. The underlying mineral is then washed off and settled.

The final tailings from a mill feed of 43 ounces will average 4.1 ounces, ratio of concentration 20-1, thus

Electricity in British Mines — Government report on the Hulton Explosion and earlier reports — Interesting new electrical winding plant in Durham — South African mines still out in favour with the investor despite continuous growth of gold output — Substantial interest evidenced in the Giesecke ball mill — What it may do on the Rand — Oil market dull — Slow petroleum developments in Russia — Falling production in Galicia — Reasons and results of extraordinary London tin fluctuations —

(Exclusive correspondence of CANADIAN MINING JOURNAL.)

London, June 21, 1911.

Electricity in mines is one of the questions that is always being debated now and the definite statement just published in the Government report on the Hul colliery explosion is particularly interesting and i portant because of its bearing on the use of electric in coal mines. The Government inspector says that is perfectly satisfied that the use of electricity in mine has no bearing on the disaster. Although t definite opinion is not read as absolving electric from being a source of risk under any circumstan it will go a long way to reassure working miners a their leaders who have not been at all backward declaring that the electric switch at the conveyor f was the initial cause of the explosion.

A Government committee was appointed to look i the whole of this class of operation as far back as 19 and a second committee in 1909 revised the rules s

by the earlier committee. It was pointed out although the accidents and ignitions arising from electrical causes were on the increase, yet, having regard to the great increase in electrical plant, the risks attending the use of electrical plant in mines were decreasing, and in no year had the fatal accidents due to electricity been greater than 1.54 per cent. of the total accidents. The risks associated with the use of electricity may be classified as due to either shock or ignition. There are two ways of attacking the shock problem. One is that of employing such a low pressure that the shock would seldom be dangerous and the other is that of employing only properly protected apparatus. The view in this country is that for all fixed plant the latter is the better and indeed the only really safe method. For portable plant complete protection should be aimed at, but having regard to the inherent difficulties in the way of totally preventing contact with live parts, it is advisable to adopt a low pressure as a further safeguard. In the case of fixed plant adequately protected, the question arises as to whether any limits should be set to the pressure under which it should work. Many think that there should be a limit, and a fairly low limit, and ten or even five years ago there was considerable justification for such a view, for at that time high tension cables and apparatus had not been as thoroughly developed as they have been since, and moreover not much attention was then paid to the special requirements of colliery electric apparatus.

The above mentioned second committee in its report stated very definitely that it saw no reason why a high pressure system should not be as safe as regards risk of shock and explosion as a medium or low pressure system. The adoption of higher pressures is moreover accompanied by some substantial benefits. A high pressure cable is thinner and lighter and more easily handled and supported than a low pressure cable of the same power, and it is generally of the highest class of construction, and provided with extra thick insulation.

The safe use of high-pressure apparatus turns upon the provision of complete protection. The only satisfactory protective system is the elementary but effective one of encasing all live parts in a substantial metallic sheath or box maintained at earth potential. A good deal of discussion has lately taken place as to the advisability or otherwise of earthing all apparatus. There are difficulties. In dry mines, particularly, good earths are often difficult to obtain, and two earth plates some distance apart may even be at appreciably different potentials until connected. If a difference of potential is maintained it will, of course, lead to the flow of current in the protective armouring, which may have objectionable results. On the other hand the risks of a difference of potential being maintained are small, except possibly in very deep or extensive mines. Armouring may be local or continuous, but the latter is much safer. Indeed, if the armouring is discontinuous a section of the armouring may, in the case of a fault to earth, become dangerously charged. To maintain armouring in continuous conditions involves systematic inspection. It is held that all electrical plant should be systematically inspected, and the absence of competent inspectors should not be admitted as an excuse.

The report insisted strongly upon the need for having all the electrical plant properly looked after, as well as thoroughly well made in the first instance. There is no doubt that competition, which has been more than usually keen in the electrical industry, had in some instances reduced strengths and proportions below a proper limit, but a considerable improvement is taking place, and the report strongly disapproved of the suggestion that the Home Office should officially approve of certain types of mining electrical apparatus. In this most engineers, if not all colliery managers, will agree with them, for official approval would certainly tend to hamper progress, which is particularly needed in the early stages of the mining electrical industry. The quality of workmanship and materials are as important as design or type; official approval could only be a partial guarantee, and would tend to relieve the colliery manager of his proper responsibility for the safety of his mining equipment.

A very interesting winding engine plant operated electrically has just been put in an important Durham colliery. The depth of the shaft is 162 feet, the time of each wind 15 seconds, the average winding speed 648 feet per minute, and the time allowed for changing 10 seconds. The winding gear is fitted with a coned drum, varying from 5 feet 6 inches to 7 feet 6 inches in diameter. The 100 b.h.p. motor is of the three-phase type, 440 volts, 40 cycles, and drives on the drum shaft through a flexible coupling and a train of machine cut helical gearing. The winder is fitted with automatic winding gear, which, in the event of an overwind, trips the main switch and cuts off the supply to the motor, and also applies the main post brakes. This gear also comes into operation in the event of failure of the supply, and is further fitted with an emergency lever, by which it may be brought into operation by hand.

The switch gear consists of an iron-clad column fitted with a three-pole oil switch with overload and no-voltage release, and an isolating switch is provided, interlocked with the main switch and the various doors of the switch column. The controller is of the rising liquid type. the control being carried out by means of one lever, which is "off" in the central position. A small centrifugal pump and motor are provided on the controller, the pump constantly delivering water from a storage tank contained in the controller bed-plate to the tank containing the electrodes. This tank is fitted with a rising and falling shutter, which is operated from the control lever, and regulates the level of the liquid in the tank. The reversing switches are mounted upon the shaft that operates the controller, and one switch is provided for each running direction. The switches are worked by means of a link motion from the control lever.

South African mines in London, although at times showing a desire to spurt, are now again completely out of favour. Yet the industry is not doing badly, although there is the usual falling off in the supply of native labour which is to be expected at this time of the year. The gold output keeps growing. Last March the record, which, owing to exceptional circumstances, had stood since December, 1908, was at last broken. In April the daily average yield was again a record,

but owing to the month being a thirty-day one the aggregate production was below high-water mark. For May, however, one has to chronicle a new record, the total of 685,950 ounces being nearly 10,000 ounces better than in March. The daily average has, on the other hand, fallen by 130 ounces. But this is much more than explained by the drop of 6,500 ounces in the East Rand Proprietary's May return, as a result of the fire on the Driefontein section. Thus the loss of nearly 4,000 "boys" from the Rand's working force last month has not yet affected working results, although it will, no doubt, influence the figures for the current month.

The midsummer Rand dividend list is satisfactory enough, a decrease in the case of the Ferreira being offset by a further increase in the Modderfontein dividend. The latter was rather unexpected considering the heavy capital requirements of the company. The Ferreira is this time only paying about what it is actually earning, the accumulated profits not being further drawn upon for the bonus which has been usual for some time past.

Great interest is being aroused in this country in connection with the Giesecke ball mill, and rumours are current as to the possibility of its displacing the present ordinary stamp batteries. It may be remembered that Lionel Phillips, in Johannesburg, on May 28th, made a reference to this appliance which, although in an experimental stage, he said, was destined to have a great influence on the future of the Transvaal gold mining industry. The inventor of the machine is now on the Rand, but particulars from his home in Germany indicate that the machine will greatly simplify the methods of recovering gold, besides making a big reduction in costs. The mill is meant to displace the ordinary stamp batteries, and the tube mills introduced on the Rand some five years ago, the crushing being completed and the ore reduced to a consisteney of slimes by a single operation. There are no screens, and the amalgamation process is also eliminated, the cyanide being applied directly as the product leaves the grinder. The ore is crushed so fine (to 60-mesh sereen) that the recovery of the gold by cyanide will be effective. The mill consists of a huge wrought-iron cylinder, about 23 feet long, over 8 feet in diameter for the first third of its length, and about 6 feet for the rest. The reduction of the ore is effected by means of steel balls, which both crush and grind it. The cylinder is divided into three compartments, and the balls in each are graded in size according to the stage of grinding, beginning with balls of about 4 inches in diameter in the first section and ending with about 1½-inch in the last. Within the cylinder are placed some ten rows of so-called "fall-plates" of heavy steel; these lift the balls and the ore about half-way up the cylinder as it revolves, when the whole mass drops upon the next plate. Water is fed in with the ore at the rate of about one-third of a ton to each ton of ore, which means a very heavy reduction in water consumption as compared with stamps.

There has been no special increase in the volume of business in the oil share market here lately. A fair sized full account exists in most descriptions. There is not much news that is fresh from the European oil fields. At Baku the relatively low returns continue, whilst at Grozny the yield in the first months of the year wears a satisfactory aspect. This area has rapidly risen from the position of an interesting petroleum region to that of an important contributor to Russia's total supply, more than making up for the decline at Baku, the importance of which looks like becoming within a measurable time simply one of inland supply and demand. Such must become the case till at last the petroleum reserves in sight at Maikop are exhausted, and it cannot positively be stated yet whether the period will be a long or a short one, or, again, whether Maikop may not yet reveal reserves of petroleum at various levels to dwarf the supplies that Baku may be able to send to the Black Sea shipping port of Batoum. Hitherto Maikop has developed very satisfactorily.

Of what is doing on the other petroleum lands of Russia not much is to be said. There are frequent reports of gusher strikes at Tcheleken, in the Caspian Sea. But little news comes through from Ferghana respecting the Tchimion Oil Company's operations. And the Government boring operations in search of payable petroleum at Uchta in the north do not appear to have yielded satisfactory results. But it is clear that these operations are on far too small a scale for forming a useful opinion. They, however, have been carried out at great expense, as the tools and plant had to be carried over many miles of hitherto untrodden land, and special houses had to be constructed for the workmen.

The falling off in the production of certain wells in Galicia has aroused particular interest, especially in view of the fact that during the last few months British capital in the Galician field has been largely increased. A well in this field costs between $50,000 and $70,000 to drill and from eighteen months to two years before the principal oil horizon is reached. Drilling, therefore, has been fairly slow. Another cause which has contributed slightly to diminish the production has been a local water trouble.

The tin position here is a very uncomfortable one, sensational rises and slumps in the price of the metal being of almost daily occurrence. The Anglo-Continental syndicate, which has been so successfully manipulating the market, has now evidently come to the conclusion that discretion is the better part of valour, and that to push its advantage to extremes would be only to incur dangers the effects of which might be disastrous. Apparently it has come to terms with the bears after unmercifully squeezing them for as long as it could do so without causing a panic. As it is, these operations are likely to have a lasting influence on the London metal exchange, and no one will be greatly surprised if one of their results is a sweeping change in the regulations affecting that organization. Already the establishment of a similar institution in Germany is threatened, and unless the London Exchange arranges to permit dealings in tin other than that of Straits or Australian origin, it is only too probable that the threat will be carried out. It is contended, with some show of reason, that the London Exchange is abusing its monopoly, and that by boycotting tin produced in the Straits Settlements or Australia it is creating an artificial shortage, which is detrimental not only to consumers, but to all the various trade interests affected.

GOLDBEARING SERIES OF LAHAVE BASIN, LUNENBURG COUNTY, NOVA SCOTIA

Abstract of report by E. Rodolphe Faribault, from Summary Report of Geological Survey for 1910.

The greater part of the district is underlain by the quartzites and slates of the Goldbearing series; but towards the north and northwest these rocks are cut by granites of Devonian age, which extend northward across South Mountain to the Annapolis Valley, and form part of the very large granite area which constitutes the backbone of the western counties of the Province. A small isolated mass of greenish grey granite was located far away from the main area, at a place situated 2 miles east of Italy Cross station, and one-fourth of a mile north of the outlet of Wallace Lake. At this locality, a recent conglomerate has been prospected for gold.

In the absence of fossils and other conclusive evidence, it has been customary to refer provisionally the Goldbearing series to the lower Cambrian, though on account of their similarity to the quartzites and slates of the Avalon peninsula of Newfoundland, which have been assigned to the Pre-Cambrian, as well as for other reasons, it is possible that they may be Pre-Cambrian.

The series as exposed in different parts of the Province has been estimated to have a total thickness of over 5 miles. This great series of rocks falls naturally into two lithologically distinct conformable divisions; a lower one, called the Goldenville quartzite; and an upper one, called the Halifax slate.

The Goldenville division is mostly made up of thick beds of grey, altered quartzose-sandstone or quartzite, locally called "whin"; interstratified with beds of dark clay slates, which are quite numerous at certain horizons, but almost wanting at others, especially at the top of the division. At many places, and more especially near granite intrusions, these rocks are much altered, and have become schistose, with a development of very minute scales of mica along the planes of schistosity, which gives them a characteristic glistening appearance when split. The Goldenville division has a thickness of over 3 miles of strata in the eastern part of the Province.

The Halifax division is composed entirely of argillaceous slates, in some cases arenaceous, and with occasional flinty layers holding iron pyrites. Dark grey layers occur sparingly, and are sometimes found to be slightly calcareous, especially when occurring at the base of the division. The lower beds are olive green in colour, and are followed by others of dark grey colour which gradually give way to a great thickness of glistening bluish-black, foliated, graphitic, soft clay slates, often pyritous, overlain by banded, black and grey arenaceous slates. The thickness of the Halifax division has been estimated at over 2 miles of strata.

After their deposition these sedimentaries were uplifted and folded into a succession of anticlines and synclines following northeast and southwest courses. They were then subjected to extensive erosion, which removed the upper part of the folds and gradually planed the surface down to its present attitude, exposing the edges of the uptilted, once deeply buried strata. The rocks, generally, dip at high angles, ranging from 45 deg. to 90 deg. from the horizontal.

In view of the intimate relation existing between the structure of the anticlinal folds and the occurrence of the gold-bearing quartz veins, special attention was paid to the location and structure of the anticlines and synclines. A section across the folds along Lahave River from Bridgewater to the old Dalhousie Road gave a succession of five major anticlines and synclines in a distance of 25 miles. Minor folds were also observed along the crest of some anticlines, especially for the first 4 miles above Bridgewater, where the strata have been plicated into a succession of small folds or undulations. Going up Lahave River the five anticlines are met with in the following order from south to north:

(1) Leipsigate Anticline crosses the river at Bridgewater, where it is composed of several minor folds in slate well exposed along the west side of the river. These folds converge westward as they approach the Leipsigate gold district, where they join and form a broad dome along which the Goldenville quartzites are brought to the surface and extend to the west. The most southerly of the minor anticlines extends eastward through the Blockhouse gold mines where the Goldenville quartzites are again brought to the surface on a smaller elliptical dome one mile long by a quarter of a mile wide. From these two domes situated, respectively, west and east of the river, the anticline pitches towards the river, forming a cross syncline which is strongly marked and extends north and south along the river, affecting the other folds similarly but to a less degree.

(2) Spondo Anticline crosses the river 4½ miles north of the first anticline and half a mile south of Mossman station. It extends eastward to the granite, passing the south end of Big Mushamush Lake and through the Spondo gold prospect, where a large saddle-shaped vein has been uncovered. Westward, it crosses Wile and Fire Lakes south of Baker Settlement. It shows nothing but slate along its whole course. A minor anticline between the above two anticlines was located in grey slate at Waterloo, where it crosses Frederick and Matt Lakes, but it could not be traced eastward to Lahave River on account of the drift.

(3) Northfield Anticline crosses the river at Northfield station 3 miles north of the second anticline. Traced eastward it crosses the north end of big Mushamush Lake and continues through Caribou Lake where the slates are superseded by the quartzites which are brought up to the surface along a broad dome extending to the granite. West of the river the anticline passes near Clifford post-office, where it converges with the adjoining north syncline in dark grey slate.

(4) Pleasant River Barrens Anticline is situated 4½ miles north of the third anticline, and crosses the river at an island 2¼ miles north of Riversdale station, where the lower quartzites appear at the surface on a westerly plunge of the fold and spread out towards the east beyond Newburn and New Cornwall to the granite. It crosses the outlet of Indian Lake and the north end of

Church Lake, where numerous cross veins and a few interbedded veins have developed. West of the river the quartzites are overlain by the upper grey slates on the transverse syncline which is here strongly marked; but, a short distance farther west, the quartzites again appear at the surface on a broad elliptical dome, on the eastern end of which the gold mining district of Pleasant River Barrens has been located.

(5) Cherryfield Anticline occurs at a distance of 9½ miles north of the fourth anticline, where it begins at the granite contact on the main river, directly east of Cherryfield station, and extending eastward, crosses the Sarty Road at the school house and the Sam Moore Road half a mile south of the bridge over North River, and ends at the granite, 3 miles farther east. This anticline brings to the surface lower beds than any other fold in the district, exposing at the surface a thickness of 2½ miles of the Goldenville quartzite, which extends southerly for 3½ miles to the Halifax slate, and northerly beyond the next syncline to the granite along the old Dalhousie Road. The strata dip at angles increasing from 25 deg. to 80 deg. on the south side of the anticline, and from 25 deg. to 65 deg. on the north, and appear to form a very narrow dome near the Sarty school house, where quartz veins have been uncovered.

Some interesting granite contacts are well exposed at a few points along the boundary line, one of which may be observed at Dog Falls on the west side of Lahave River, below the bridge, half a mile north of Cherryfield station. As a general rule the quartzites are altered quartz-mica schists, but the strata show no local disturbances as a result of the granite intrusion.

Evidence of dislocation and faulting has been observed, however, at many places, especially in the vicinity of large projections of the granite into the sedimentaries, but the disturbances are apparently the result of movements that took place subsequent to the irruption of the granite. At Upper New Cornwall—between Otter Lake, the northeast end of Big Mushamush Lake, and the south end of Church Lake—the strata are much disturbed, and there is probably an important fault running northerly in the direction of Union Square, Morton Corner, and Sarty, along which the western block has moved south with reference to the east one. Towards the south, this fault probably runs along the eastern shore of Big Mushamush Lake and passes through Slaughenwhite Island and Farmville towards Blockhouse. Along this course much brecciated country rock and quartz is shown. The cross veins operated at Blockhouse are probably a zone of fractures on the southern extension of this fault.

Economic Geology.

Gold.

Leipsigate Gold District.—Two gold mining districts, Leipsigate, and Pleasant River Barrens, are situated in the area surveyed. A detailed survey of Leipsigate was made in 1904 and a report on that district was included in the Summary Report for that year, pages 321-329, together with a plan on the scale of 500 feet to 1 inch, published separately. After 1904, operations were continued until 1908 on the Micmac fissure vein by the Micmac Gold Mining Company, and a depth of 596 feet has been attained. When in operation the Micmac mine proved a good producer, and there is every reason to believe that under good management it should still continue to yield well. In 1905 and 1906 some work was also done at the Owen mine on the vein. A little prospecting was done in the nort part of the district by Simeon Erust and others, no important discovery has been made since the su of 1904.

Pleasant River Barrens Gold District.—The dis is situated in Lunenburg County, on the Pleasant R Road, 15 miles north of Bridgewater, between R and Shingle Lakes, on the eastern end of a broa liptical dome of quartzites, which is 4 miles long miles wide, and is surrounded and overlaid by slates of the Halifax division. The auriferous qu veins occur at the outer edge of the dome in slate ers interstratified between thick beds of quar (which often stand out prominently and form a cession of parallel ridges with intervening swa curving gradually around the eastern part of the d and dipping towards the southeast, east, and north at angles of 20 deg. to 40 deg. The district has l idle for the last twelve years, hence only a cursory amination could be made of the old workings. Sev veins have been uncovered, a few of which have developed, but none of them have been exploited, cept to a limited extent. The more important veins the Dunbrack, Mill, Pine Tree, Brignell, Ernst, Bent leads. A specially rich but narrow pay-streak worked for a short time on the Dunbrack lead at intersection of an angular vein dipping north 60 One fissure or cross vein, was also discovered by Ja Deal, crossing the strata in a southwesterly direct Most of the work was done in the eighties and nine and three stamp-mills are reported to have erected.

On the east side of the river, gold-bearing veins h been uncovered and prospected at several places, the results obtained appear to have been unsatis tory. The most important veins developed are following:

On the southeast side of North River, 2 miles eas Meisner post-office and three-fourths of a mile east O. Acker's house, a vein was discovered in 1892 Thomas Acker, and worked by a Windsor company a depth of 40 feet; a five-stamp mill was built and tons of ore crushed, but the prospect was finally ab doned. The vein is 1 to 10 inches thick, dips north deg., and is interbedded in altered quartzite, in c tact with the granite. In 1909 a few other para veins were prospected by David Lawrence.

At Upper New Cornwall, at Rocky Point on t northeast shore of Big Mushamush Lake, two ve were opened in or about 1888 by Freeman Millet, slate between walls of quartzite. On the north v there is a pit 21 feet deep, and on the south one, t pits 24 feet deep, but the whole prospect is now flo ed by the lake.

Farther north, half a mile south of Indian Lake, the east side of the road, a vein 12 inches thick cutti across the quartzite was prospected by W. H. Pr with two shafts 25 feet deep, and some ore was crush at the Blockhouse mill. Numerous other cross vei have been located between this prospect and the fo of Indian Lake along the fault passing in this vicinit Ore-shoots may possibly occur at the intersection some of these cross-veins with the interbedded vei which are found along the Pleasant River Barre anticline at the foot of Indian Lake and the north e of Church Lake.

Copper.

ver twenty years ago, at Dalhousie East, Kings nty, situated 10 miles northeast of Springfield sta- o on the west side of Crossburn Road and three- ths of a mile north of Old Dalhousie Road, a shaft wa sunk to a depth of 165 feet on a copper-bearing ve in granite. At the surface the vein appears to st ke S 25 deg. E magnetic, and dip vertically. Sam- pl picked up at the mouth of the shaft show the ore to e chalcopyrite and chalcocite in a gangue mostly co posed of granite and quartz. An analysis of the sa ples made at the Mines Branch gave 1.05 per cent. of netallic copper, but did not show the presence of go l, silver, nickel, tin, or tungsten, for which elements th were tested. Irving Smith, who occupied the fa n on which the shaft was sunk, and also worked at th mine, furnished the following information: The ve a was discovered about the year 1876 by Ainslie W son, and the shaft was started in 1890 by a Bridge- w er company. The shaft measures 14 by 8 feet, is 16 feet deep, and is timbered to a depth of 100 feet. A the cropping the vein was 12 inches wide, and pr ved rich to a depth of 20 feet, where large crystals of quartz were found, after which it decreased in size ar value, and at the depth of 100 feet it began to dip to ards the east, and its size became less than 2 inches. A a depth of about 20 feet, a drift was driven 12 feet on way and a few feet the other. The vein has not be n traced at the surface, because its outcrop is prob- ably of very limited extent; as in the case of the King ve n at Lake Ramsey, near New Ross. Drift of similar or is reported, however, to have been found half a mile fa ther north in the direction of the vein, half way be- tw en Irving Smith's present house and Sixtymile L ke, where also traces of copper were found on an ou crop of granite.

Iron Ochre.

A deposit of yellow and red ochre was found at A burndale, along Heckman Brook, on the west side of L have River, and 4 miles north of Bridgewater. The d posit is said to be 1 to 2 feet thick, and 50 tons taken fr m John Penney's farm were shipped to Halifax in 19 8.

Whetstone.

A quarry of slaty rock suitable for the manufacture o whetstones was opened in 1901 by George McFaden, o Bridgewater, at Parkdale, Lunenburg County, at the ou let of Whetstone Lake, 9 miles northeast of New Germany. The rock is composed of beds of hard, greenish, grey, siliceous and argillaceous slate, occurring at the base of the Halifax slate division; the strata dips south at an angle of 75 deg. After about two years' operation, McFaden sold the quarry to a Maine company, which continued operation for a short time, and erected a building for machinery, which, it is said, never reached the quarry on account of financial difficulty. The quarry is now 3 to 6 feet deep, 12 feet wide, and 25 feet long.

Tin and Manganese at New Ross.

At New Ross, Lunenburg County, some distance east of the district surveyed last summer, two important veins, one bearing manganese and the other tin and copper, were opened last summer.

A vein of manganese recently discovered by Ernst Turner in granite, 2 miles to the north of Wallaback Lake, and 8 miles north of New Ross, has been opened by a Windsor company, under Dr. H. W. Cain's management, with a shaft to a depth of 145 feet; and it is reported, with very satisfactory results. The vein varies in width from 4 to 18 inches and dips nearly vertically. The ore, which carries streaks of red hematite near the surface, is found to be exceptionally free from iron at a lower depth. An assay of some samples gave only 0.1 per cent. of iron, with 5 to 6 per cent. of carbonate of baryta. A similar vein of manganese, occurring at a distance of 1¼ miles to the south, was exploited a few years ago by Dr. Cain, but has not yet been reopened.

A tin-bearing vein, also recently discovered by Ernst Turner, at Mill Road, 4 miles north of New Ross, has been prospected under the management of A. L. McCallum. It has been proved to a depth of 20 feet, and for a length of 250 feet, while the float has been traced half a mile towards the north. The vein is 24 inches wide, mostly made up of quartz, merging with granite at the sides, and carries at the middle a streak of rich ore from 3 to 5 inches wide. Several assays of the ore made by Mr. McCallum have given from 10 to 30 per cent. tin, and 8 per cent. copper, present in the form of cassiterite and chalcopyrite, with association of tungsten-bearing and zinc minerals. Several other veins occurring in this vicinity, and showing copper, molybdenite, etc., have not yet been prospected.

Tungsten.

A new discovery of tungsten ore, in the form of scheelite, has been made by W. H. Prest, at Middlefield, Queens County, near the Fifteenmile Brook gold mine, and prospecting was started last fall in order to trace the float to the parent vein.

International Geological Congress

12TH SESSION, CANADA, 1913.

Coal Resources of the World.

OTTAWA, May, 1911.

For some years the attention not only of geologists d mine owners, but also of the general public, has en directed to the question of the coal reserves of the rld. The very large increase in the consumption of al in recent years makes this question of the world's pply of great importance to almost every country. he Eleventh Congress dealt with the iron ore reserves the world, calling attention to the fact that, along with coal, the iron ore supply is one of the most important factors in industrial development, and to the radical importance of the relation between supply and demand in these materials to the industry of the future.

The Executive Committee of the 12th Session of the International Geological Congress, to be held in Toronto, in 1913, has, therefore, decided to make coal the chief subject for discussion at that session. In order to obtain a sure basis for the discussion and to secure a profitable result, the committee would like to have

the co-operation of colleagues in every country, so that they may publish statistics of the amount and distribution of the world's supply of coal. With this end in view, we have decided to address to the proper authority in each country, a respectful request that there be sent to us for publication a concise report on the geological occurrence, extent of the coal areas, and amount of the reserves in that country.

The statement should include:—

(I.) Coal of economic value contained in seams of workable thickness, situated within a mineable distance of the surface.

(II.) Coal of economic value contained in seams of workable thickness, situated beyond present mineable distance of the surface, but possibly of future availability.

In Group I. should be given coal in seams containing not less than 1 foot of merchantable coal occurring not more than 4,000 feet below surface, including workable submarine areas.

In Group II. should be given coal in seams containing not less than 2 feet of merchantable coal occurring not less than 4,000 feet and not more than 6,000 feet below the surface or submarine areas not included in Group I.

Since estimates of quantity may differ in exactitude, both groups should be subdivided into: (1) Actual Reserves, including cases in which the calculation of the amount is based on a knowledge of the actual thickness and extent of the seams; (2) Probable Reserves, including cases in which an approximate estimate only can be arrived at; and (3) Possible Reserves, including cases in which an estimate in figures cannot be given. Thus:—

In columns 1 and 2 returns should be expressed in figures. In 3 a general statement should be made, "Large," "Moderate," "Small." All quantities in columns 1 and 2 should be given in metric tons.

In order to have the various reports uniform and easily comparable, a standard classification has been adopted, to which, it is respectfully requested, the matter of each report should be made to conform. A chapter summarizing the chief results will be prepared by the committee, but each report received will appear separately.

This classification is adopted as a simple basis on which the desired information can be received and correlated. The committee recommend a discussion by the Congress, looking to the adoption of a universal standard classification.

The reserves of coal of each of the following classes or subdivisions of classes should be given in conformity with the above schedule. It is hoped that the characteristics mentioned under each class and subdivision of class will enable authors to place in its proper class not only a well known coal, but even a coal that may not have been closely studied.

Class A.

(1) Burns with short, blue flame; gives off 3 to 5 per cent. of volatile combustible matter.

$$\text{Fuel ratio} \frac{\text{Fixed carbon}}{\text{Volatile matter}} = 12 \text{ and over}$$

Calorific value 8,000 to 8,330 calories, or, 14,500 to 15,000 British Thermal Units.

GROUP I.

Including seams of 1 foot or over, to a depth of 4,000 feet.

District	Coal Seams		Actual Reserve. (Calculation based on actual thickness and extent.)			Probable Reserve. (Approximate estimate.)			Possible Reserve.
	No of	Thickness.	Area	Class.	Metric tons.	Area	Class.	Metric tons.

Ballantyne	.....	.....	.....	.....	.....	150 sq. m.	.....	.....	B_1 large. A_2 moderate.

ean composition,

Carbon	93 to 95 per cent.
Hydrogen	2 to 4 per cent.
Oxygen and nitrogen	3 to 5 per cent.

) Burns with slightly luminous, short flame and litt smoke; does not coke and yields from 7 to 12 per cent. of volatile matter.

uel ratio, 7 to 12.

alorific value generally 8,330 to 8,600 calories, or, 15,00 to 15,500 B.T.U.

ean composition,

Carbon	90—93
Hydrogen	4—4.5
O and N	3—5.5

Class B.

))Burns with short, luminous flame and yields 12 o 15 per cent. volatile matter; does not readily co. Fuel ratio 4 to 7.

alorific valne generally 8,300 to 8,900 calories, 15,- 20 to 16,000 B.T.U.

ean composition,

Carbon	80 to 90 per cent.
Hydrogen	4.5 to 5 per cent.
O and N	5.5 to 12 per cent.

2) Burns with luminous flame and yields from 12 to 6 per cent. volatile matter; generally cokes.

uel ratio 1.2 to 7.

alorific value 7,700 to 8,800 calories, 14,000 to 16,- 00 B.T.U.

ean composition,

Carbon	75 to 90 per cent.
Hydrogen	4.5 to 6 per cent.
O and N	6 to 15 per cent.

3) Burns freely with long flame; withstands wea- th ing but fractures readily and occasionally has mois- tu content up to 6 per cent.; volatile matter up to 35 per cent.; makes porous, tender coke.

Fixed carbon + ½ volatile
——————————————=2.5 to 3.3.
Hygroscopic moisture + ½ volatile

alorific value 6,600 to 7,800 calories, 12,000 to 14,- 00 B.T.U.

lean composition,

Carbon	70 to 80 per cent.
Hydrogen	4.5 to 6 per cent.
O and N	20 to 30

Class C.

Burns with long, smoky flame; yields from 30 to 40 per cent. volatile matter on distillation, leaving very p ous coke. Fracture generally resinous.

Calorific value 6,600 to 8,800 calories, 12,000 to 10 000 B.T.U.

Class D.

ontains generally over 6 per cent. of moisture; dis- in grates on drying; streak brown or yellow; cleav- a indistinct.

1) Moisture in fresh-mined, commercial output up to 20 per cent. Fracture generally conchoidal.

Drying-cracks irregular, curved lines.

Colour generally lustrous black, occasionally brown.

Fixed carbon + ½ Volatile
——————————————=1.8 to 2.5.
Hygroscopic moisture + ½ Volatile

Calorific value 5,500 to 7,200 calories, or 10,000 to 1,000 B.T.U.

Average composition,

Carbon	60 to 75
Hydrogen	6 to 6.5
O and N	20 to 30

(2) Moisture in commercial output over 20 per cent. Fracture generally earthy and dull.

Drying cracks generally separate along bedding planes and often show fibrous (woody) structure.

Colour generally brown, sometimes black.

Calorific value 4,000 to 6,000 calories, or 7,000 to 11,000 B.T.U.

Average composition,

Carbon	45 to 65
Hydrogen	6 to 6.8
O and N	30 to 45

The reports should include not only a statement of the location and distribution of the various deposits (if possible, illustrated by means of maps and sections), but should deal with such chemical and physical qualities as are determinative of their technical utilization.

For the rest, every writer is free to act as he thinks fit, though it is very desirable that his statement should not exceed the dimension of — quarto pages of print.

The choice of language is limited to French, German and English.

It is the intention that these reports, together with the chapter prepared by the committee, shall be published before the end of 1912, so that every one interested may make use of them for all purposes, and particularly for the discussion at the meeting of Congress. Under these circumstances it is specially desirable that the separate reports reach us before January 1, 1912.

We, therefore, address ourselves to you, in the hope that you will contribute to the investigations referred to, by drawing up a comprehensive survey of the occurrences of coal in

---

We feel sure that the plan we have presented will gain your interest, and that you will not refuse us the benefit of your valued co-operation, and we beg you to rest assured of our gratitude for the assistance that we feel confident you will give us.

All communications on this subject should be addressed to the General Secretary of the Twelfth Congress, R. W. Brock, Director of the Geological Survey, Ottawa, Canada.

G. G. S. Lindsey, Convener.

Committee on Coal Resources of the World, appointed by the Executive Committee of the International Geological Congress, Twelfth Session.

The Quest for an Ideal Stope Drill

Mr. E. M. Weston, A.S.M.E., after giving the reasons for the failure of various stope drills in the Rand competition, commented as follows on the deductions made by the Stope Drill Committee in their report: (1) "Hammer drills are not at present suitable for the general stoping conditions which obtain on these fields; that is to say, for down holes the reciprocating drill has proved its superiority." One must remember that as far as the hammer drill itself is concerned there are a very large number of one type of hamm-

drill successfully at work on the Rand and several others being successfully introduced, so that the weakness does not lie with the drill, but with the means employed for ejecting the broken cuttings, which included hollow steel. The inference is that if these difficulties could be overcome we have ready to hand a man drill weighing from 50 to 70 pounds.

(2) The second deduction is: "That hollow steel is not at present recommended, the class of material used in its manufacture not being suitable. It is a high-priced article, but it appears to crystallize more rapidly than the cheaper solid steel, and gave more difficulty in tempering, which process, however, was carried out by smiths used to the cheaper material ordinarily employed." Progress is continually being made in the manufacture of hollow steel, and at the present moment I believe the first statement of No. 2 does not apply. Steel used in the bulk of the piston drills in use on the Rand carries about .6 per cent. carbon, and, though not as hard as it might be, can be carelessly heated and tempered by plunging. Already, however, as a result of the experiments carried on at the Robinson Deep, steel of .7 per cent. to .75 per cent. carbon is recommended for some work. Steel of this temper requires more careful heating and tempering, and it has long been known that the slap-dash save a penny a hundred in sharpening costs and send the steel below with the minimum amount of labour and trouble expended on it methods do not pay. Mr. Tom Johnson, in his report, indulges in some plain, but not too plain, speaking with regard to the methods in vogue. Until recently all hollow steel was high carbon steel with .7 per cent. and over, I believe, and such steel should be carefully heated and should have the temper drawn, as is done in the case of picks; and the adoption of these methods, though they might add a few white blacksmiths to shop staffs, would scarcely ruin the mines, as the saving in costs of cutting rocks would run them into thousands against an expenditure of hundreds. Every other progressive mining field I know of has proved this and acts on it. However, today steel makers are prepared to supply hollow steel of any temper required, and steel can be procured of .69 carbon exactly similar to that in use in piston drills. It is also stated that one manufacturer has a secret process somewhat similar to that employed in the manufacture of Mannesman piping.

At any rate, hollow steel in long lengths, with a hole as large as ¾-inch in 1¼-inch round steel, is now on the Rand, and holes have been bored with it by both piston and hammer drills on the surface, and experimental holes are now being drilled underground in a Rand mine. This steel per foot of length as used to make drill bits (jumpers) is cheaper than solid steel. The committee express themselves unfortunately in stating that hollow steel appears to crystallize more rapidly than the cheaper steel. What they might have written was that hollow steel was used in hammer drills and in them it tends to crystallize more than solid steel does in piston drills. As a matter of fact, steel used in either piston or hammer drills gives little trouble from this cause if it be annealed once a month. Boring with high air pressure in piston drills in shaft sinking in some of the hardest diabase on the Rand, I have seen solid steel of two carbon contents, owing to the intense vibration, crystallize so that I broke as many as 50 shanks with 12 rock drills in six hours, and the high carbon steel stood better. It is, however, true that the vibrations set up by hammer drills striking 1,000 to 1,500 blows per minute tend in hard gro to cause breakages from crystallization. This trou has been increased from two causes.

The hammer drill manufacturers do not know t the real requirement of the Rand in the matter o one-man drill is for a really simple light drill that native can understand, and will like. which uses o 30.50 cube feet of air at 70 pounds pressure, and wh will put down a 4-foot hole, starting with about in diameter and finishing about 1-inch. Now, whet such a drill puts down four, six or eight holes in shift does not matter so much as the fact that suc machine would do the work of at least four nati and do it better than they would, and relieve labour shortage on the Rand and in Rhodesia, while the same time stopes could be kept ready now blasting with large charges, and using 6 or 7-f holes, which are the conditions under which the p ent small piston stope drill works would be avoid Hammer drill manufacturers strive to produce chines with a maximum boring speed. Though it well known that one can get any boring speed likes as long as the steel will stand (in other wo that the resisting power of the steel in any gro must be the determining factor in hammer drill sign), it is amusing sometimes to note the rival cla for boring speed among the various manufactur and as soon as one maker produces a machine that bore, say, upper holes at a reasonable speed, anot introduces a machine that delivers a heavier or m rapid stroke on the plea that it will bore faster. der such conditions one must expect that the resist powers of the long-suffering drill steel must soon severely tested, and a return be made to machines signed to drill at the highest economical rate cons ent with the size of steel used in them and the air p sure and hardness of the ground.

Tin Corners on the London Metal Exchan

(Translated from the "Cologne Gazette" of June 1

During the past year we have frequently had oc sion to call attention to the movements in the pr of tin, and especially during the last few days to present unsatisfactory state of affairs. A small gro of financially strong speculators, who already at beginning of last year successfully forced up pric have now succeeded by withholding supplies in fecting a corner in tin, which began in February a now reaches its highest point this month. In Feb ary, 1911, the price of three months' tin was on average about £187 10s., whereas the cash price w £190 3s. The difference between the cash and th months' quotations remained about the same duri March and April, but in May it reached £10, th £19, and on the 9th June even £42. Cash tin was p for at up to £233, whereas the quotation for th months was only £191. At the present moment tin prompt delivery is quoted at £231, and for delivery three months £190. The possibility of bringing abo a condition of affairs so extremely harmful to regul business, and the temptation to such manœuvres in the tin contract adopted by the London Metal E change.

The determining factor as to whether tin may delivered against contracts is not its quality, but origin; that is to say, tin must be produced in t

its Settlements or Australia (both British colon-
Prudent members of the London Metal Exchange
of course, perfectly aware that a state of affairs
as at present prevails is quite incompatible with
standing and influence of the London Metal Ex-
ge, and consequently are thinking of means to
e a recurrence more difficult. A movement is,
efore, on foot to alter the tin contract in such a
as to admit to the market tin other than Straits
Australian. Due, however, to the conservative
s of the English, the delivery of other kinds of tin
ing made as difficult as possible, and heavy deduc-
s are made for tin of other origin, as compared to
delivered in the past. Consequently in practice
delivery of tin from other sources than hitherto
vered will only come into question when there is
in an artificially created shortage of tin for prompt
very. The new contract will make it more difficult
in the past to effect illimitable corners. The only
cal method would be to introduce a contract which
ely does away with the question of origin, and
prescribes a definite quality. The quality can be
exactly both mechanically and chemically. (It
be mentioned that there are already in London a
ber of assayers recognized by the Metal Ex-
ge). Nevertheless, the present proposition of a
London merchants would be an advance upon the
state of affairs, provided some absolutely neces-
alterations are made.

cording to the present proposals, there will be de-
rable in future tin from Banka and Billiton as well as from China and England, with varying deductions according to the purity of the tin. This purity is to be ascertained by an assayer recognized by the Metal Exchange, and his certificate for this and for the other details of quality is to be affixed to each warrant. German tin is the only kind to be excluded. This is all the less explainable, as the production of tin in Germany forms a considerable part of the world's production, and is steadily on the increase. In 1910 the production of tin in Germany amounted to 11,000 tons —that is, about two-thirds of the English production and about 10 per cent. of the world's production. The attempt to exclude German tin from the market can only be put down to some small-minded business reasons and to an unhealthy Chauvinism. It may be expected from the Committee of the London Metal Exchange, whose quotations are taken as the basis for the trade all over the world, that they will not allow themselves to be influenced by such attempts, but, being fully aware of the responsibility of their position in relation to the trade of the whole world, irrespective of nationality, will act up to it. All the incidents of late and the movement depicted above, show, however, how necessary it is to establish on the Continent an institution holding the balance to the London Metal Exchange—let it be in Berlin, Hamburg, or Amsterdam. The manner in which the London Metal Exchange abuses its monopoly can only hasten the creation of a new exchange elsewhere independent of London.

The By-Product Coking Process and its Future Development*

By Mr. Ernest Bury, Skinningrove.

he writer has chosen this title for discussion by
son of his belief that the by-product coking indus-
has thoroughly justified its inception, and that the
e has now come to enquire into the future possi-
ties of the process.

y-product coke ovens cannot be said to have had
ery rosy time in our country, and criticism of the
ustry has been unnecessarily harsh. Since Messrs.
se & Partners led the way at Crook in 1881, there
until quite recent years been a never ending war
inst the more economic manufacture of coke. It
been variously alleged that the coke from by-pro-
t coke ovens was inferior to the produce of the old
-hive ovens, and that the recovery of by-products
ng with the production of a first-class metallurgi-
coke, was impossible. These statements have, by
son of the big development in the by-product cok-
industry, proved absolutely untrue. In 1898 the
ount of coal carbonized in by-product coke ovens in
at Britain was 1.8 million tons per annum, it is
over 8 million tons. With regard to the unsuit-
lity of by-product coke for furnace use, the writer
of opinion that now nothing more may be said, and
old prejudice may be laughed at.

During the last year the plaint against by-product
ustry has taken on a different hue. It is not now a question of unsuitability of the coke produce, but this large amount of by-product development is going to be the ruin of us, and by-products are going to suffer. This is an unconscious compliment to the industry, whose coke product was supposed to be unsuitable, but let us enquire into the grounds for dread. The most important and valuable by-product from coke ovens is sulphate of ammonia, representing as it does from 1/7 to 3/- net per ton of coal carbonized. The following figures of yield taken from the Blue Book of the Chief Inspector of Alkali Works, together with the average prices, show how little the big development in coke ovens during the last seven years has affected the prices of the principal by-product.

Year.	Total production of Sulphate from By-Product Coke Ovens. Tons.	Total production of Sulphate from all sources. Tons.	Average price per ton of Sulphate of Ammonia. £ s. d.
1903	17,435	233,664	12 9 2
1904	20,848	245,990	12 3 8
1905	30,732	239,114	12 10 9
1906	43,677	289,391	12 0 9
1907	53,572	313,281	11 15 8
1908	64,227	325,228	11 12 0
1909	82,886	349,143	11 5 0
1910 Returns not yet to hand			12 3 2
Present Price			13 6 0

*Paper read before the Cleveland (England) Institution of Engineers.

Since in 1891, the price of sulphate of ammonia was only £10 17s. 6d., i.e., at a time when the sulphate produce from by-product coke ovens did not exceed 5,000 tons per annum, the extensive growth of the by-product coke oven, coupled with other sulphate recovery works (the gas industry, blast furnace and producer gas processes), can hardly be said to have threatened the value of the main by-product. The answer to the apparent paradox is the growing appreciation and demand for sulphate of ammonia as a fertilizer for cereals, sugar, and vine growing, all three important articles of food. With the food supply at stake there is little chance of this product from coal being put in the background. The only danger would be a cheaper fertilizer, and this is not forthcoming. Certainly there is the possibility for atmospheric nitrate (i.e., nitric acid electrically produced from the atmosphere and combined with lime), but given this possibility, and its production is not great except with very cheap power, there is room for the two products, in the consideration of the world's food supply.

As regards tar and benzol, the other products obtained from by-product coke ovens, there has again been an upward recent tendency. Tar has risen from 16s. to 21s. per ton, and benzol (90 per cent.) from 6d. to 9d. and 10d. This again, the writer would suggest, is due to fresh fields and pastures new. Tar has found an outlet for road dressings, and benzol has developed as a motor spirit, the result being a shortage for the old outlets, which have had to bid against the new usages. In fact, the by-products process depends for its future developments, as do all other processes on fresh applications for its products, and to this end the writer offers to the meeting the following considerations:—

The future of the by-product coking process lies (1) in the development of the process itself, (2) in the application of the process.

Developments in the Process Itself.

Recent years have brought forth many improvements which have helped to establish the process. Flue arrangements have been perfected, whereby regular heating of large coking chambers is produced, the result being even carbonization with minimum repairs to oven lining. It is safe to say that with a modern design of heating flues coupled with the choice of a first-class siliceous firebrick, the minimum life of a by-product coke oven lining may be taken at four years, and the chance of serious breakdown in this direction such as have occurred in the past, may no longer be considered.

The growing possibilities of coke oven gas as a source of towns' illumination, power generation, furnace heating and the like, have furthermore led coke oven inventors and designers to perfect regenerative systems of oven heating whereby the process has been resolved into a highly developed heat economizer, so that where 60 per cent. of the gas evolved was required by waste heat processes for oven heating, an equivalent quantity is now available for any desired extraneous purpose.

Before proceeding, it may be of interest to you to see the design of a by-product coke oven, which is now being erected by the Otto Hilgenstock Coke Oven Company, at Skinningrove, which in the writer's opinion embodies the modern drift of coke oven design. From the illustration you will see that in the first place the gas is admitted to alternate sections of flues, not from a common gas flue or duct, but by independent burners which are accessible and interchangeable from the c- side. By this means there can be no mis-direction f the heating gas, and the temperature of the oven w- remains even throughout. In the second place, si- the products of combustion, having passed up one s- tion of flues, are drawn down the adjacent flues, s much heat is transferred to carbonization duty as p- sible. There is, furthermore, the advantage that products of combustion, instead of collecting in a c- mon flue at the top of the oven wall, thereby tending overheat the oven crown, are immediately withdra and superheating of the crown is minimized. The generators, which are 15 feet deep, are tall and narr and no opportunity is afforded the gases to cut acr corners, which is the case with squat regenerat Finally, you will observe that the depth of the carb- izing chamber is considerably higher than the de of the flue chambers. Most of you who are in co- oven practice, will admit that the crown of all c ovens gets too hot by radiation from the mass of coke during the latter stages of carbonization, an fect which is harmful, since it produces breakdown gases, tars, benzol, and ammonia. By increasing depth of coal beyond the flue depth, the aforesaid diant heat will be absorbed in the upper thickness coal, which, of course, will be carbonized, resulting a greater all round output of coke, gas, and by-produ per oven with no further expenditure of heating g and at the same time giving a cool crown with grea yields per ton.

The writer believes that, as regards the design the carbonizing chamber itself, very little remains to accomplished, except that where the consideration coke oven gas for any use is of moment, the chamb might be heated by producer gas (regenerated if n be) instead of by coke oven gas as at the present ti Such method of heating was suggested by the wri at the Dublin meeting of the Institution of Gas En- neers in 1907, and would open up, by employment modern mechanical producers, the large quantities refuse small coal which are still thrown to waste, left in the pits, in many parts of this country. T writer is informed that at one plant in Westphalia coke oven battery is already heated by producer g from refuse coal, and suggests that there are ma cases in Great Britain, the need for coke oven gas ing urgent, where this method of heating would tend national economy. When all is said and done, it only the method employed for heating towns' gas torts throughout past generations.

The writer has suggested that the design of constr tion of coke oven carbonizing chambers has nea reached its zenith in the type of oven just describ but the chemical aspect of the process offers a far m extensive territory for development and economy. T last two years may be truly said to have marked epoch in carbonization practice, since inventors ha been driven from the worked-out field of oven desi to investigate economies and developments in deali with the gaseous products resulting from their ov as carbonization chambers pure and simple. The writ refers, of course, in the first instance to the attem which have been made to recover sulphate of ammo direct on the gas main, without having recourse to t usual method of condensation of ammonia liquor, a the subsequent distillation of the latter in the ma facture of ammonium sulphate. To students of co oven economy, it has always appeared wasteful to c down from the gases the aqueous vapours contain

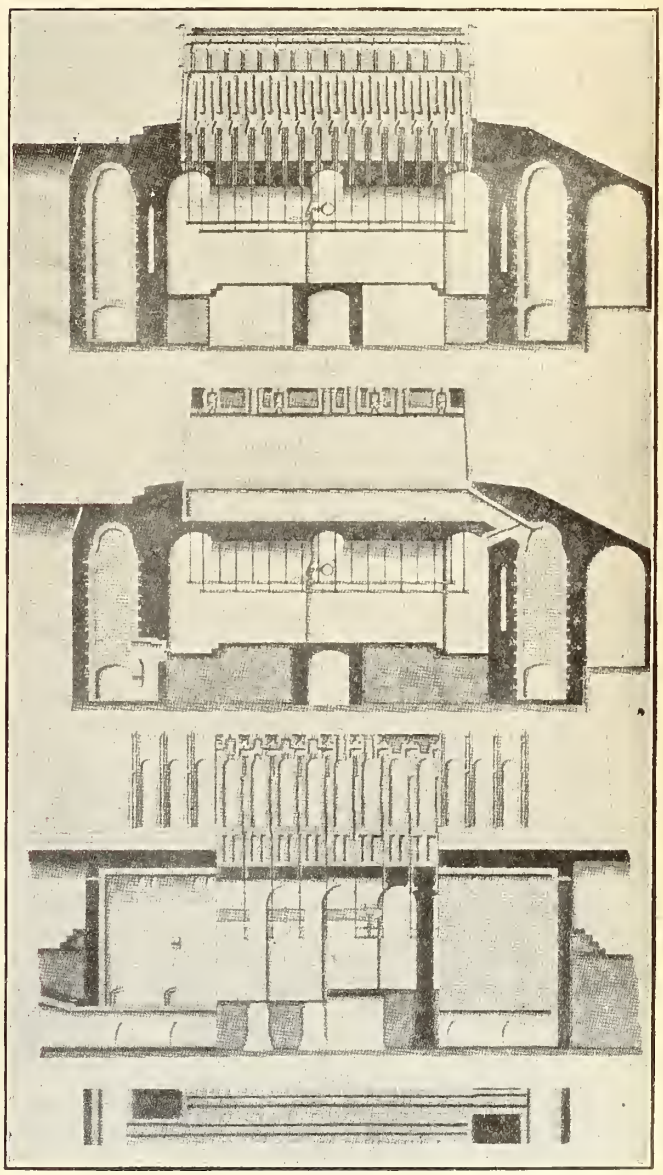
monia, forming part of the distillation products of ovens, and afterwards to reheat these aqueous ducts to recover ammonia or ammonium sulphate. a procedure was the reverse of fuel economy, and cordingly Brunck, in 1903, sought to pass the hot uncondensed tarry gases from his coke ovens direct through sulphuric acid. Brunck's aim was ethically right in seeking to conserve the heat contained in the hot gases from the ovens for the manufacture of ammonium sulphate, but unfortunately his object was baffled, in so much as the acid became tarry and dirty sulphate was the result. Furthermore, the tarry products exerted a reducing action on the sulphuric acid, and the sulphurous acid gas produced corroded his gas mains. The entire process therefore became unworkable.

The next attempt at direct sulphate recovery was made by Koppers. This inventor avoided Brunck's method of attempting to treat the hot gases, and decided to cool out his tars in the usual manner before the sulphuric acid washing. The vessel containing sulphuric acid or saturator, as it is called, is inserted as a scrubber, through which the tar-free gases are passed, thus eliminating the chances of loss of ammonia which might occur with liquor or water washing in the usual type of scrubber. The liquors which have condensed in the process of tar removal (containing with wet coal about 80 per cent. of the ammonia) are heated with steam in an ordinary ammonia still, the ammonia and steam from which are passed into the saturator on the gas main. In order to avoid condensation within his saturator, Koppers preheats his gases after tar removal, by passing them before entering the saturator through a "reheater" or "heat exchanger," through which is passed the hot gases travelling from the ovens to the condensing plant. By his invention, Koppers avoids using the scrubbing water ordinarily employed, thus reducing the amount of liquor requiring to be treated by the ammonia still, and therefore, the amount of river polluting effluent which is of serious moment in some parts of the country. Koppers' salt is of good colour and contains a minimum amount of tarry matter.

The most important development in the treatment of coke oven gases and in the recovery of tar and sulphate, is that devised by Dr. Hilgenstock of the Otto Company. The inventor reverts to Brunck's original aim, but instead of passing tarry gases into sulphuric acid, he primarily removes the tar from the hot gases by passage through a tar spray, the temperature of which is so regulated as to completely remove the tars without effecting condensation of the greater bulk of ammonia liquor. From the spray, the gases containing the liquors in steam form, together with the ammonia, are passed directly into sulphuric acid, where the ammonia is caught and precipitated as ammonium sulphate. The gases leaving the saturator are free from ammonia, but still contain the liquors as steam, which is carried on to the ovens and boilers and thus disposed with.

In the event of the gases being required for benzol recovery, gas engine use, or towns' lighting, the Otto Company employs a fractional method of condensation, whereby the greater portion of the liquor containing very little H_2S, etc., is precipitated immediately below the dew-point. The remainder of the liquor obtained by completion of the cooling is similar to ordinary spent liquor without, however, containing any lime; its amount is so small that it can be mixed off with the coke slacking water.

The next three diagrams and photographs of models will show the extent of these recent simplifications in the recovery treatment of coke oven gases. It will be seen from the illustrations that Otto's new process dispenses with condensers and water for the same, liquor circulating pumps, liquor cellars and stores, ammonia stills and superheaters, lime mixer, lime pump, settling tanks for spent liquor and drains therefrom, steam connections and boiler power, thereby effecting a big economy in ground space. The working costs are reduced by abolition of steam and lime in sulphate making, and trouble in dealing with spent liquor. Finally, all chances of loss of ammonia are reduced to a minimum, since the free or volatile ammonia never leaves the gas main, and losses by circulation and in the distillation process are avoided.

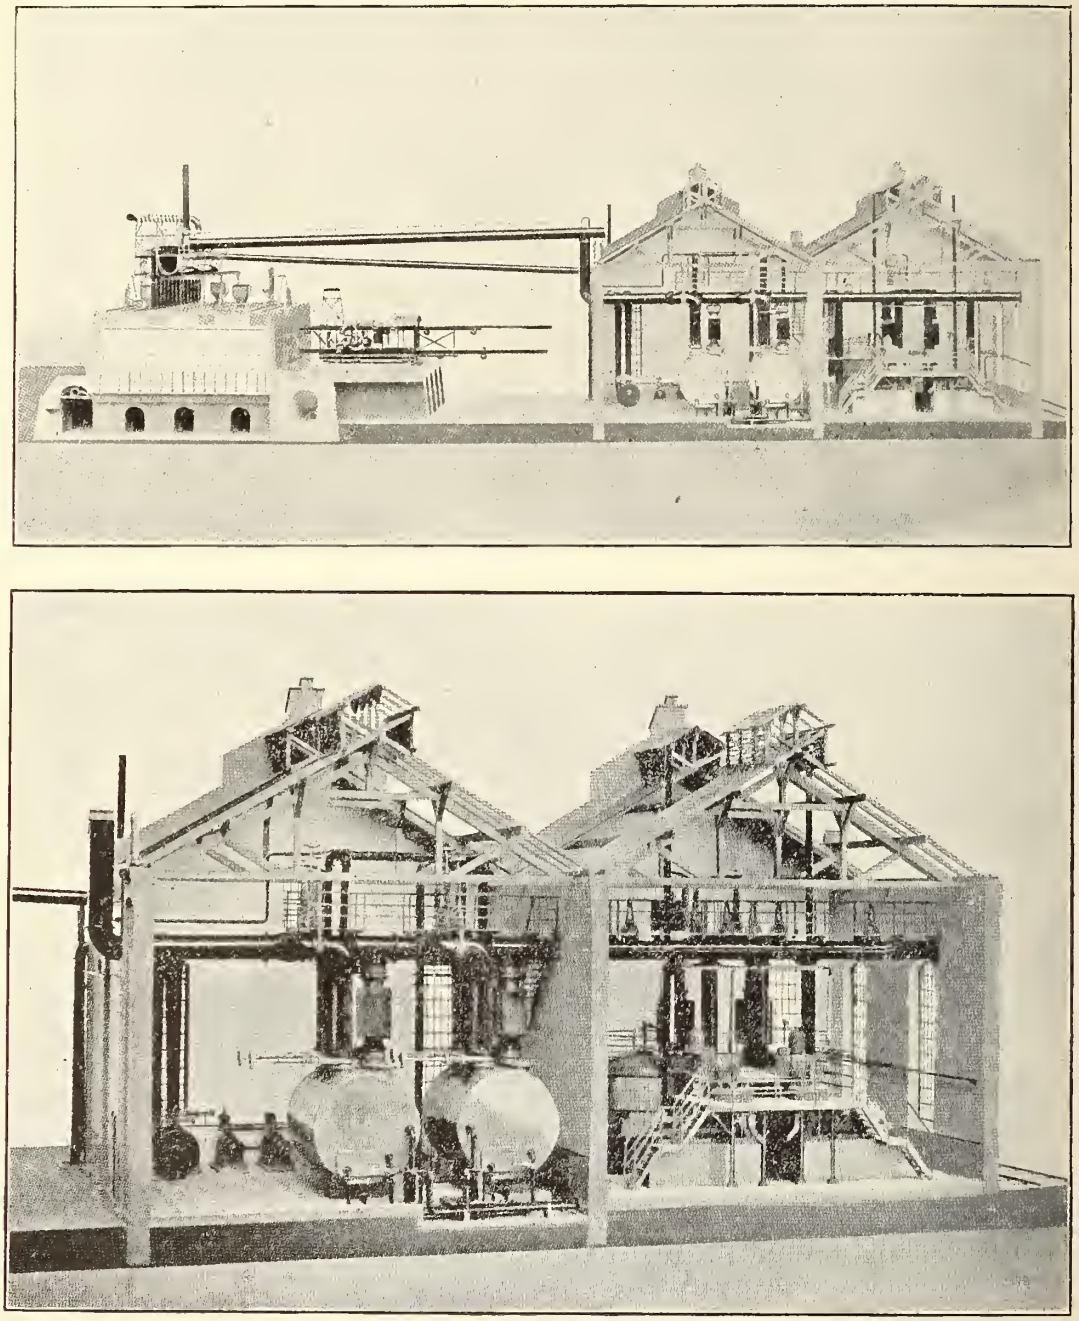


Regenerative Coke Oven

Several points have been suggested against the Otto method of recovery from the hot gases. In the first place it has been stated, that the temperature of the gases, and the reaction heat produced by the ammonia and sulphuric acid in the saturator was insufficient to prevent condensation in the latter, and that external steam had to be supplied to avoid such condensation.

The writer has found that this point turns on the percentage of ammonia present in the coal; very small quantities of condensings containing fixed ammonia salts are produced in the foul gas mains and sprays, and these have to be worked off in the saturator. If the amount of ammonia in the coal is below the equivalent of 1 per cent. of sulphate, the reaction heat in the saturator is insufficient to evaporate these condensings when put into the saturator, and a small amount of steam has to be supplied to the vessel to keep up the temperature. If the sulphate of ammonia exceeds 1 per cent. the reaction heat is sufficient to evaporate the condensings without need for supplementary steam. Under the worst conditions the writer found in Westphalia that one ton of steam per ton of sulphate made was required for the Otto saturator, and since eight tons are required for heating up the liquor from the old recovery method, Otto's worst conditions may be said to have effected very great economy. At Auchgeich, the first Otto direct recovery plant in Great Britain, where the yield of sulphate of ammonia is approximately 1.5 per cent. on the coal, the writer found the following temperatures:

Gas entering sprays	93 deg.
Gas entering exhauster (after sprays)	65½ deg.
Gas leaving exhauster	66 deg.
Gas leaving saturator	70½ deg.
Gas delivered to ovens	62 deg.



Otto-Hilgenstock Direct Recovery Process

It will thus be seen that so far from the saturat losing heat, the temperature rises, and there is no nee for the application of auxiliary steam in evaporatin the condensings, and this is the case for all coals co taining 1 per cent. of sulphate and over.

It has been further alleged that the Otto sprays c

*Gain in temperature by reaction heat 4½ deg. C.

completely remove the tars, and that dirty sulphates would result as in the case of Brunck. The best answer the writer can give to this statement is, to submit a sample of sulphate which he collected at Auchengeich, which speaks for itself. At the six plants which the writer visited in Westphalia, the highest percentage of tar found in the sulphate was 0.22 per cent., the lowest 0.07 per cent., as compared with 0.06 per cent. in sulphate made by the old process.

Some gas engineers have thought, that by the passage of the gas through sulphuric acid, the calorific value would suffer, presumably through absorption of heavy hydrocarbons, ethylene, and benzine. At Auchengeich the writer found the following calorific values on successive days:

596
602
599 } b. t. u. Gross per cubic foot.
608
581

Since modern London coal gas averages about 580 b.t.u. gross, the writer is of opinion that the weak solution of acid in the Otto saturator has no solvent action on the gas.

It has likewise been suggested that at the temperature of the gases leaving the spray, both naphthalene and benzol will be carried forward with the gas. This, the writer found, took place to some extent, but does not consider it of moment, since, with coke oven plant recovering benzol, both products are brought out by the solvent oil. If the gas is required for town's lighting, the benzol contributes to the value of the gas, the naphthalene being removed by one of the usual solvents. With regard to the question of naphthalene, it may be added that one of Krupp's plants working on Otto direct recovery system, is to be used as town's gas works for Bochum, so that no naphthalene trouble is anticipated in this instance.

In the writer's opinion not one of the least important applications of Otto's new process lies in the facility which it affords for the recovery of ammonium chloride from those coals containing a high percentage of common salt. In such event, the condensings found in the foul gas mains would be collected and concentrated for the recovery of ammonium chloride without passing them into the saturator for conversion to sulphate. The price for ammonia as ammonium chloride is much higher than when combined as sulphate, so that the natural disadvantage of a coal in containing much common salt may be turned to profitable account in this instance.

The Burkheiser Process.

The next important attempt at coke oven economy has been put forward by Burkheiser, who proposes to utilize the volatile sulphur contained in the coal for the manufacture of the sulphuric acid required for the sulphate of ammonia recovery, incidentally effecting purification of the gases en route. As a general rule the amount of volatile sulphur given off in the form of H_2S from most coals will produce more sulphuric acid than required for sulphate of ammonia recovery, the average amount of sulphuric acid obtainable being 40 pounds per ton of coals.

The next illustration shows a diagram of Burkheiser's arrangement. The gases coming from the ovens are cooled in the usual manner, the tar and liquors being completely separated from the gas. The liquors are then distilled in the usual type of ammonia still, and the evolved ammonia returned to the gas main. The dry tar-free gases containing the whole of the ammonia and H_2S, are then passed forward to a small oxide purifier, where the sulphuretted hydrogen is removed by a specially active form of iron oxide prepared by Burkheiser. This purifier is duplicated, one always being at work on the gas main, the other meanwhile undergoing a rapid re-oxidation or re-vivification by a current of air. By this latter process, the iron sulphide formed in the purification is re-oxidized to oxide of iron, the sulphur going forward as SO_2, which is caught in an "air-scrubber" through which is passed the mother liquor to be described shortly. From the working purifier on the gas main, the gas free from H_2S passes into the saturator, which is fed with saturated liquor from the scrubber, into which the gas passes after leaving the saturator. Precipitation of ammonium sulphite takes place in the saturator, the salt is whizzed and the mother liquor drainings are sent to

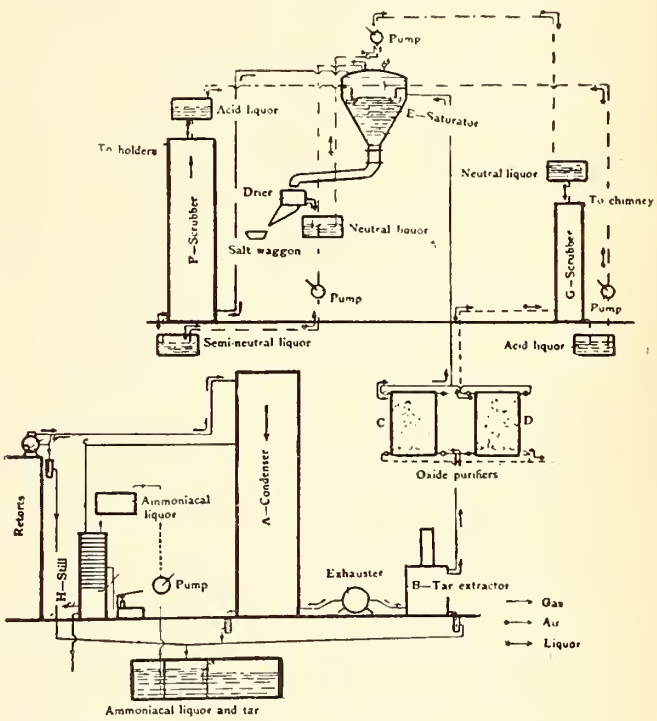


FIG. 1—DIAGRAMMATIC SKETCH OF BURKHEISER PLANT

the "air-scrubber" to take up more SO_2 from the revivifying oxide. In the air-scrubber the neutral ammonium sulphite in the mother liquor takes up SO_2 according to the following reaction:

$$(NH_4)_2\ SO_3+SO_2+H_2O=NH_4.HSO_3+NH_4.HSO_3$$

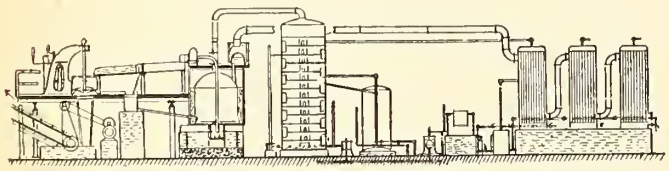
This acid ammonium sulphite solution is then sent to the ammonia scrubber through which are passed the gases coming from the saturator. Here the acid ammonium sulphite takes up the last of the ammonia, forming some neutral ammonium sulphite, and then into the saturator, where it is met by the bulk of the ammonia in the gas to be treated. In the saturator, the acid sulphite is completely changed to the neutral ammonium sulphite, which precipitates out in the manner aforesaid, the mother liquor being returned to the air-scrubber to take up more SO_2, and so on to repeat the cycle of operations.

The ammonium sulphite is converted to ammonium sulphate by repeated sublimation and oxidation in a

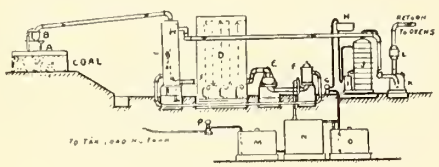
revolving drum. Burkheiser has improved on this, his original scheme, by passing his SO_2 from the purifiers together with excess of air over strongly heated iron oxide in a contact chamber, and thus converting the SO_2 to SO_3. On subsequently washing the gas with this SO_3 liquor, he obtains ammonium sulphate direct, without need for oxidation of the sulphite as in the former instance.

The writer submits for your inspection a sample of ammonium sulphate which he took from Burkheiser's plant at the Hamburg Gas Works.

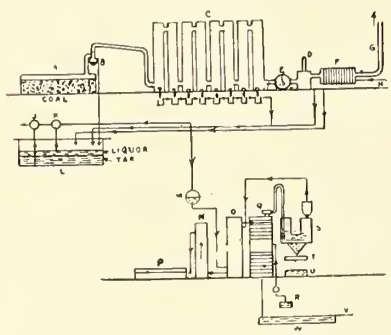
There are several important points about Burkheiser's process which are of interest to everyone connected with carbonizing plants of any kind. In the first place the natural sulphur content of the coal is utilized to manufacture sulphuric acid for sulphate re-



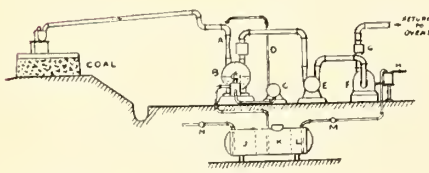
SULPHATE OF AMMONIA STILLS AND ACCESSORIES.



KOPPER'S PROCESS



OLD PROCESS



OTTO PROCESS

covery representing a sum from 30s. to 35s. per ton in the cost of manufacture of the latter product, besides affording a home made supply to those plants distant from sulphuric acid works. Secondly the recovery of sulphur or purification of the gas is accomplished in small vessels, thus avoiding the heavy cost of large ground space entailed by the usual massive box purifiers universally employed at gas works. The process is of particular interest to those who are confronted with sulphur troubles in dealing with coke-oven gas for large gas engines. Burkheiser's small purifiers would be of great benefit in such cases, even if the SO_2 were turned to waste and unrecovered, on account of their small first cost and the saving in ground space afforded.

Applications of the Process.

The Utilization of Coke Oven Gas for Town's Light

In spite of the big developments in America a Germany which have gone forward in the applicat of coke oven gas for the lighting of townships, v little has been done in the same direction in this co try. As long ago as 1901, Dr. Schniewind descri well established coke oven gas works at Everett, H ilton, Camden, and Sparrows Point in the Uni States; other works have followed at Milwaukee Detroit, and the movement has gone ahead. In G many at the present time progress in this directio extremely rapid, and many towns are arranging to t their supply from coke ovens. An important review this subject appeared in a recent issue of the Tir Engineering Supplement, pointing out that 212 mill cubic feet of gas of the quality usually supplied towns are daily wasted by the coke ovens of the R Basin, which at the low price of 7d. per 1,000 cu feet, represents a sum of £2,000,000 per annum. Es and Mulheim have commenced to utilize this waste closing down their town's gas works, and relying coke oven gas solely, the price of the gas wholes being 8½d. per 1,000 cubic feet. Bochum has follow suit by taking the gas from Krupp's Hanover and H nibal Collieries. Barmen, Velbert, and Heiligenh have likewise made contracts for the supply of c liery gas, and many others have made arrangemer or are negotiating to a similar end. In all, about million cubic feet per annum have been already plac

There have been a few isolated cases in this coun where coke oven gas has been employed for this p pose, but British gas engineers have not yet seriou considered the by-product coke oven as a possible to their industry. There are many instances wh collieries or blast furnaces possessing coke oven pla already provided for as regards their own power quirements, are situated near to large towns, and these cases the application of coke oven gas for tow lighting might with advantage be carefully looked to. The writer does not suggest that as a gas-maki machine, the by-product coke oven is the equal of modern gas retort. The point is, that as a commun we are carbonizing coal for two purposes. (a) F the manufacture of town's gas, coke being the by-p duct. (b) For the manufacture of metallurgical co gas being the by-product. From the point of view the economy of coal supplies, the two processes over so that if the by-product in either instance, coke or g respectively, can be substituted, a step towards nati al economy will result.

During the past generation, the main ambition the gas industry itself has been to derive from mother coal the maximum amount of gas obtainat and to this end gas engineers have devoted themsel to devising retorts which would produce the great amount of crackling of the volatile matters. A table instance of this development is the vertical tort, whereby 12,000 to 12,500 cubic feet of gas made per ton, compared with 10,000 to 10,500 cu feet when distilled in the old horizontal retort, i.e. very important movement to conserving our coal su plies. This development has only been made possi by the invention of the incandescent mantle, where the thinner gases made under more economical c ditions, may be made to give out three times amount of light for a given consumption of gas. T combined effect of the gas industry's progression m

be xpressed, that the yield has been increased by 20 cent., and that the total gas yield produced has turned to three times better account.

s a result of these economies, there has been gen- revision in the methods by which illuminating gas ow valued, and by the introduction of the Metro- an No. 2 Argand Burner, a large amount of gas is ow available, which before the invention of the descent mantle, would not have been admissible for town's lighting Already some 130 gas authori- ties have by the Standard Burner Bill, availed them- selves of power to supply gas under the new economic conditions, and the country may now be said to be free from the old candle-power superstitions, and in a position to make the most of the coal in the production of ghting gas.

rom the point of view of our paper, the progress made by the gas world has opened up large possibili- ties for those coke oven plants with surplus gas avail- able, which are situated in the neighbourhood of large townships. With the care of a gas manager bestowed on a modern coke oven installation, there is no diffi- culty in making town's gas of modern standard. I make bold to say that there is no plant which could not either by supply of the whole gas, by fractionation, or by enrichment, prove of great financial benefit to an adjacent community. The usual method by which the coke oven manager disposes of his gas is by burn- ing it under boilers, that is a purpose for which raw coal without carbonization charges, and expensive plant, would be equally suitable. At the colliery, re- fuse coal would replace the use of gas under boilers, and the value of the latter fuel for steam raising would not exceed 0.8d. per 1,000 cubic feet. At works to which coal would have to be transported, the steam raising value of the gas might be double, say 2d. per 1,000 cubic feet. Even if these figures are increased by 50 per cent., the present value is small compared with the cost of town's gas into the holder. The aver- age cost of town's gas put into the holder at 60 gas works in this kingdom averages 1s. 1d. per 1,000 cubic feet, which offers a handsome margin, after deducting cost of oxide purification (0.5d. per 1,000 cubic feet) between burning coke oven gas under boilers and us- ing it in the town's main. There is ample room for a gain to the coke oven plant, and a substantial reduc- tion to the consumer, and a good deal of overlapping in the matter of coal consumption would cease.

n the above the writer has mentioned the "frac- tionation" of coke oven gas in the consideration of its supply to towns. By this is meant the separation of the richer gases evolved during the earlier stages of car- bonization, for despatch to the town, the poorer gases during the latter stages being retained for oven heat- ing. This was the method employed by Schniewind in the United States, at Everett, Massachusetts, and is also employed by some coke oven gas works in Ger- many. In this matter and in the question of enrich- ment likewise, the quality of the coal, and the manner in which the carbonization is carried out, determines the course to be adopted. With very lean coals, one or both methods may have to be employed, in order to keep up the value of the gas. With richer coals, no fractionation, or enrichment is necessary in order to provide gas of present day standard. In the case of the Little Hulton Bill, with which the writer has been associated throughout, the quality of the whole gas made complies in every particular with the desired standards, and is, in fact, identical in character with the gas supplied in the Metropolis, and made by mod- ern vertical retorts, as will be seen from the following table:

	Brackley Gas	Coal Gas supplied by one of the Metropolitan Companies				Gas from Glover-West Vertical Retorts.
CO_2	2.15	1.48	1.75	2.11	2.85	1.00
O_2	0.31	0.25	0.52	1.05	0.20	0.05

Illuminating power by Metropolitan No. 2 Argand burner, at 5 c.f. per hr.	16.0	18.6	18.21	14.48	14.65	15.56

From time to time objections have been launched against coke oven plant as a source of towns' supply. Recently a paper was read by Mr. J. S. Lucking, of Clay Cross, before the Midland Association of Gas Managers, which pointed to the unreliability of coke ovens as a source of towns' illumination. He says that "coke ovens are not worked so regularly as gas retorts, and when the ovens are stopped for three or four hours, it is often 36 hours or more before there is any surplus gas." This, no doubt, was the case in this particular instance, but the writer has not experienced any such serious irregularity. The obvious precaution of any coke oven plant taking upon itself the responsibility of supplying a township, is to so duplicate all the run- ning plant, that breakdowns and stoppages are re- duced to the safety margin provided by gas works themselves, and this the writer has found neither diffi- cult nor costly, when the advantages of continuous and steady running are considered. Mr. Lucking raises no point against the quality of coke oven gas, for which he gives the following analysis:

CO_2 0.5%
CO 9.0%
Unsaturated Hydrocarbons 3.0%
H_2 47.7%
CH_4 26.2%
N_2 13.0%

Calorific value=550 b.t.u. gross.
Minimum Candle Power=14.

In view of these considerations, the writer is of opin- ion that as regards the supply of gas to towns, there are many instances in which the coke-oven industry may be held to have future prospects. Metallurgical coke which cannot be made in gas retorts has to be produced, and since coke oven gas now comes within the class of towns' gases, it may be expected to be no longer a wasted by-product, but of use to metallurgi- cal communities. For instance, if Middlesbrough were supplied with coke oven gas at 6d. per 1,000 cubic feet into the holder, the township would be saved approxi- mately £7,000 per annum in the manufacturing cost. There are many coke oven plants who would be glad

to dispose of their gas in bulk to townships at the price named.

The Utilization of Coke Oven Gas for Power Development.

The writer has had no personal experience of very large gas engines running on coke oven gas, but desires to point to the rapid development in this direction which has taken place in recent years in Germany. It is true that the application of coke oven gas for this purpose is not so extensive as has been the case with blast furnace gas, but this is mainly for the reason that coke oven plants are set down as a rule at collieries, where the domestic need for power is not so great as at ironworks, where often big developments are in progress. The high percentage of hydrogen in coke oven gas is often alleged as the reason for the non-development of this branch of coke-oven possibility, and true it is that coke oven gas engines have to be run on lower compression than is the case with blast furnace gas. Nevertheless, this drawback has not debarred German engineers from utilizing coke oven gas wherever expedient. The Augsburg-Nurnberg firm alone has 49 engines, averaging 1,290 b.h.p., or a total of 63,270 b.h.p., employing coke oven gas solely. These engines, representing a capital expenditure of from £350,000 to £400,000, may surely be said to have placed coke oven gas for engine use beyond the pale of risky experiment. One firm, the Eschweiler Bergwerks Verein, has increased its installation step by step as follows:

2 Engines,	520 b.h.p.	=	1,040 b.h.p.
2 Engines,	1,110 b.h.p.	=	2,220 b.h.p.
1 Engine,	1,160 b.h.p.	=	1,160 b.h.p.
2 Engines,	2,330 b.h.p.	=	4,660 b.h.p.
2 Engines,	2,660 b.h.p.	=	5,320 b.h.p.

Total 14,400 for one station.

This should be sufficient proof of the practicability of coke oven gas driving.

Messrs. Enrhardt & Sehmer have erected 15 engines, developing a total of 17,980 b.h.p., all of which are running on coke oven gas, and at Heinitz, one of their stations, 7 engines are at work developing 11,000 b.h.p. At this latter plant, the annual average gas consumption is 0.57 cubic metres per b.h.p. hour, the composition of the gas being as follows:

CO_2	2.8%
O_2	1.0%
CO	7.6%
Unsaturated Hydrocarbons	3.7%
H_2	50.3%
CH_4	24.9%
N_2	9.7%

On this basis a modern regenerative coke oven plant carbonizing 400 tons of coal per day, would be capable of developing 5,000 b.h.p. Even by supposing only a yield of 50 per cent. surplus gas, and 25 cubic feet per b.h.p. hour, the total power output would be 3,300 b.h.p. for a plant of this size.

The writer believes that a large number of the troubles entailed in the use of coke oven gas, over and above those dependent on engine design, have lain in the want of thorough preparation of the gas before use.

The removal of tars and naphthalene, both of which produce valve troubles, is readily effected by a combination of modern tar extractors in the first instance, and by anthracene washing in the second (the latter being simultaneous with the removal of benzol). The sulphuretted hydrogen which would burn to SO_2 producing corrosion in a heavily water-cooled engine, may be removed either by the usual box-purifier containing oxide of iron, or by Burkheiser's method previously described. Apart from the purification itself, it is of advantage to remove the sulphuretted hydrogen from the gas for the manufacture of the sulphuric acid required by the sulphate of ammonia plant, so that the removal effects a double end. The maximum amount of tar allowed in the gas in German practice is 0.2 grm. per cubic m., and total sulphur 0.3 grm.

The Use of Coke Oven Gas for Furnace Heating.

The employment of coke oven gas mixed with blast furnace gas or producer gas, for the heating of smelting furnaces, is yet in its infancy, but the possibilities in this direction of a large iron and steel plant with by-product coke oven batteries as auxiliaries are not to be denied. If it is assumed that such a plant depends for its power on gas engine development throughout, it is quite within the bounds of probability that surplus gas will be available from both blast furnaces and coke oven plant, which, in the absence of town's gas schemes, would be available for furnace heating. To some extent this is already being done at Kattowitz, in Upper Silesia, where a mixture of coke oven gas and producer gas has been employed since 1906, with large economies in producer coal as a result, and Krupp's have recently adopted the Kattowitz method.

A mixture of three parts blast furnace gas and one part average coke oven gas would pan out as follows:

CO_2	9.0 %	
CO	22.75%	
H_2	13.25%	
CH_4	7.50%	
C_2H_4	.50%	(C_6H_6 having been removed from the coke oven gas).
	44.00%	Total combustibles.

the calorific value being 260 b.t.u. Average producer practice would give a gas between the following limits:

CO_2	= 3 to 6%
CO	= 22 to 28%
H_2	= 9 to 14%
CH_4	= 2 to 3.5%

or a calorific value of from 125 to 175 b.t.u. Say from 33 per cent. to 44 per cent. total combustibles. The only point in which the composite gas would be lacking would be the tars and soots which ordinarily pass over with the producer gas into the furnace. The calorific value of the tars is equal approximately to 11 b.t.u. per cubic foot of gas, thus raising the calorific value of best producer gas to 186 b.t.u. per cubic foot. This addition, however, does not increase the calorific power of best producer gas to the calorific power of the composite gas given, so that the loss of the tars in the latter are not of moment from a calorific standpoint. It may be objected that the absence of the tars might render the composite gas less luminous and more difficult to control in the furnace, but the writer would point out that washed Mond gas is successfully being used for furnace heating. It is also probable that when the composite gas is highly regenerated its high content of CH_4 with the small amount of ethylene it contains, would render the flame sufficiently luminous for its easy control.

mentioning this use for coke oven gas, the writer ly alive to its high hydrogen content, and the ble dangers resulting therefrom. Needless to say, by the employment of such a "composite" as sug- d the mixture of coke oven and furnace gases d have to be carefully regulated and governed. A haphazard mixture would be fatal to its success.

The advantages to be derived from following up this or coke oven gas are:

Substitution of the producers and the cost of work- he same and a gas of constant composition free steam, the latter being a contingency attendant most producers with a resulting cooling and oxi- dizing effect upon the furnace.

For the rest, given the successful application of this or coke oven gas, steel plants would be run on the us surplus from the blast furnace side, an aim to which our president referred in his opening address, which would result in an economy of 2s. to 3s. per f steel. A battery of coke ovens carbonizing 400 of coal per day, would produce sufficient surplus when mixed with three times its bulk of blast ace gas, to replace the ordinary producers required he manufacture of 1,700 tons of steel per week.

The Utilization of Benzol as a Motor Fuel.

During recent years the low prices ruling for benzol discouraged coke oven owners from its recovery, in most cases benzol has been allowed to pass for- with the gases as boiler fuel. At plants where is an abundance of cheap fuel this has always ared to the writer to be wasteful, though possibly me cases where there was a big demand for power, fuel prices were high, there may have been little ain by benzol recovery. The trouble has lain in a ieted market for the product. With the exception e relatively small quantities of benzol which are for solvent purposes, cleansing and the like, prac- ly the whole of our benzol goes to the dye industry. e has been little competition for the product and s have remained low.

Quite recently, however, there has been an upward ement, owing to the growing use of benzol for road rs. France has created a market for our product his direction, and the large quantities of benzol h are now being exported to that country have d the price of 90 per cent. benzol from 6d. per n to the present figure of 9d.—10d. In our own try, there has been nothing in the nature of a gen- movement for the employment of benzol in motor cles, though Messrs. Sadlers, of Middlesbrough, one or two other firms have made a start in this ction. Needless to say, some hard things have been against the new motor fuel, as is usual with all lties, and motor benzol is having a hot time. Pos- the vested interests may be at the root of the urbance, and the criticism may be unfair.

The writer has manufactured and had some experi- of the use of benzol in road motors of many s, and has found that where due regard is paid to greater density of benzol, that superior results are ined over the foreign product. Coke oven benzol sesses a specific gravity of 0.885, whereas the specific gravity of petrol ranges from 0.68 to 0.78. This being case, benzol contains a greater weight of combus- per unit volume, and, therefore, requires a greater unt of air for its perfect combustion. The sooty s and valves which have been complained of when g benzol, have been due to an entire disregard of essential point. With an auxiliary air supply on the induction pipe these troubles completely disappear. The greater density of benzol has likewise been a source of trouble to the unscientific chauffeur from a mechanical standpoint, since in the float carburetter a more rapid cut off of the fuel is effected by the denser benzol which leads to an insufficiency of supply to the cylinders. By a careful balancing of the carburetter float with suitable weights, the greater density of the benzol may be readily overcome, with the result that a greater weight of combustible is admitted to the engine, which, with the extra air supply before mentioned, will produce a far more effective result than is the case with the lighter spirit, petrol. Both petrol and benzol are sold per unit volume (i.e., per gallon), so that with petrol of gravity 0.7 and benzol 0.882, 1.82 pounds increase in weight of combustible are obtained per gallon in the case of benzol, i.e., an increase of 26 per cent. Making due allowance for the superior difference in calorific values of petrol, a net inducement of 20 per cent. is left to the consumer, reckoned on the volume content. As regards price, petrol is variously retailed in this country at 1s. 1d. to 1s. 3d. per gallon. Allowing 2d. per gallon to the middleman for handling, this would leave the wholesale price of petrol at 11d. to 1s. 1d. per gallon. Since benzol has now crept up to 10d. per gallon wholesale, there seems to have been a considerable amount of levelling up between the two commodities, which with continued perseverance on the part of benzol manufacturers is likely to last, but benzol could rise still further when recognized as a motor spirit.

The foreign interests have had numerous complaints to allege against the claims of the British spirit. It is stated to be highly sulphurous and therefore corrosive to motor engines. The writer prepared benzol containing 0.14 per cent. CS_2 against which this complaint was made, yet many cars have run continuously on such benzol for two years without any corrosive effect having been made manifest. It is not well to call the kettle black, but petrol is not altogether free from taint in this particular, as much as 0.1 per cent. to 0.2 per cent. of sulphur being present in the foreign spirit on some occasions. The last straw alleged by the opponents of benzol has been its foul smelling exhaust products. This is, indeed, calling the kettle black, petrol itself is not pleasant smelling; as regards this point, it is entirely a matter of usage. Exception has also been taken to the relatively high freezing point of pure benzol, whereby difficulties transpire in cold weather. On a few occasions the writer has met with this trouble, but by lowering the freezing point by admixture with naphthas, this difficulty has been overcome. In fact, in this connection, with suitable carburetters, crude coke oven naphtha may ultimately serve as a reliable motor spirit.

In order to set all doubts at rest concerning the applicability of benzol for motor use, the writer would suggest that comparative trials be made between petrol and benzol by the Automobile Association. The uses of benzol in internal combustion engines are not restricted to road motors. We live in an age in which air ships have been conceived, and the need for a national motor fuel is urgent. The writer is of the opinion that coke ovens will play an important part in this direction when their possibilities are fully realized.

The Use of By-Product Coke in Suction Producers and Stoves.

In many parts of the country, anthracite is extensively used in suction producers. Anthracite being a

searce commodity, its price is necessarily high. The writer has been driven to employ by-product coke made from bituminous coal in its stead, and would commend to those depending on anthracite, this future use for the produce of by-product coke ovens. Anthracite prices range from 25s. to 35s. per ton, compared with coke from 12s. to 18s., and the power development for this class of work obtainable from the two grades of fuel is altogether out of proportion to the difference in price. In Lancashire, the writer substituted coke for anthracite; the prices were as 12s. is to 33s., and the power developed as from 90 is to 100 respectively, ratios which speak for themselves. The main point in the substitution of by-product coke for anthracite, lies in the provision of a larger grate area in the former instance, whereby a larger surface of the lighter and harder fuel, coke, may be afforded to the ingoing draught. With hard burned coke no more scrubbing is required for coke-producer gas than is the case with anthracite, and perfeetly even running throughout months of work is ensured.

The writer has also found, that in the case of the domestic stoves which are coming into fashion, the same principles hold, that given sufficient grate area, coupled with sufficient depth of fuel, by-product coke will take the place of anthracite at a much redueed cost per calorie.

Finally, the writer would refer to the possibilities of by-product coke ovens as a solution for the conservation of coal supplies, and for the smoke problem. To many of you these questions may have beeome hackneyed, and to others they may even appear chimerieal, but whether we like it or not, the day when they will have to be considered is bound to come. That they are correct in theory no doubt can exist, and their practieal treatment will follow. Up to now few methods h been advanced for the ready combustion of h burned coke in household grates, and there has a tendeney towards the production of a soft low t perature domestie coke, e.g., coalite, which would suitable for grates of ordinary design. In the writ opinion this movement is retrograde, since it ent the production of large quantities of paraffiny tars w small yields of gas of very high candle power. By inception of the incandescent mantle, the need fo high candle gas is no longer of moment, and a la quantity of gas, in view of its application for power lighting purposes, is of more value to the country a whole than a large quantity of tars. Making due lowance for our requirements of tar-derivatives for textile industry, medicinal products, antiseptics, r treatment, etc., the aim of all carbonization proces should be, to obtain as much gas from as little coal possible, and since this entails (by the high tempe tures necessary for such gas production) the manuf ture of a hard coke, we must seek some means utilize the latter, and more economically produced f for every possible purpose. This is not so insupera as the tendency towards coalite production would h us believe. It is true that closed stoves would have be employed, and central heating, or a composite and coke fire might be essential, but all of these worth the trouble in the consideration of coal econo The change may not come about until as a race, deeide to abolish the blazing eoal fire, but that tim bound to eome, although legislation may be the l resort. When this new era in coal economy arrives, a all coal has to pass through a carbonization stage, by-product eoking process will lay still further cla to national utility.

The Problems of Tungsten Concentration

By H. C. PARMALEE.

The mining and milling of tungsten ores has been a growing industry in Boulder County, Colorado, since 1900. In the early days of gold and silver mining in this district the tungsten minerals were unrecognized, and they received various names from the prospeetors and miners. In general they were regarded as forms of iron, and were considered without value. In 1900, however, the first production of tungsten oeeurred, amounting to 40 tons of ore valued at $3,216. Since then the production of high-grade ore and eoneentrate has inereased annually, except during a depression in 1907-8.

The output for 1909 amounted to 1,100 tons of high-grade ore and eoncentrate, valued by the United States Geological Survey at $396,000. The total output in the United States for the same period was 1,607 tons, valued at $559,500. From this it will be seen that the Boulder County produetion is by far the most important in this eountry, amounting in 1909 to about 70 per cent. of the whole. In 1910 the output from Boulder was 1,530 tons of high-grade ore and eoneentrate, valued by the State Bureau of Mines at $736,700. During the same period the output of all other metals in the county was valued at $161,589.

The tungsten minerals in the Boulder field are three iron-manganese tungstates, ferberite, hubner and wolframite, and the calcium tungstate, scheel Ferberite predominates, but scheelite oeeurs in ma mines, as is shown by the occurrenee of lime in t analyses of ore and concentrate—there being no otl source of lime worthy of consideration. These min als are of high speeific gravity, scheelite being 6 a the other three ranging from 7.1 to 7.5. They are g erally soft and friable. The ferberite oecurs in th rather well defined forms which, however, frequen grade into each other. These are (1) Well-erystalliz crusts and layers covering the surface of rock fr ments and cementing them together; (2) massi granular ore occurring in more dense seams; and (the highly silieious ore in which ferberite occurs in fi grains scattered through the gangue.

In breaking ore in the mine the highest grade sorted and shipped without preliminary milling. present this grade must average 40 per cent. or mo tungstic acid. The lower grades, ranging from 3 p cent. to 15 per cent. tungstic acid, are concentrated wet methods. Two grades of concentrate are recover and shipped; the first contains 60 per eent. or mo tungstic acid, and the second ranges from 35 per ce to 40 per cent. The former is usually recovered coarse concentrate and the latter as slime.

*Reprinted from Metallurgical and Chemical Engineering.

The stability of the tungsten industry depends, of course, on the uses for the metal; and as these are not extensive and the demand is limited and variable, there always the possibility of intermittent operation of mines and mills. It is safe to say that were it not for the large companies operating in the Boulder district the industry would have a more variable career than it now enjoys. At the present writing there is a large tonnage of unused concentrates in the Eastern market, as well as at the mills, with no immediate demand in sight. The principal use of the metal is still confined to the manufacture of tungsten steel for high-speed tools. Minor quantities are used in dyeing textiles, glazing pottery, colouring glass and paper, making bronze powder, and weighting silks. The manufacture of tungsten electric lamps creates a slight demand, but a ton of high-grade concentrate will suffice for the manufacture of 15,000,000 to 18,000,000 lamps the quantity used is not important.

The reader who may be interested in other details of the Boulder County tungsten field, such as general and economic geology, mining, technology, ores, etc., is referred to the Colorado Geological Survey, which has published a complete report, from which some of the foregoing information has been abstracted.

Location of Mills.

The town of Nederland is centrally located with respect to the tungsten mills of Boulder County. It is reached by stage, 18 miles from Boulder, or by railroad to Cardinal station and thence by stage for 2 miles. At Nederland is the mill of the Wolf Tongue Mining Company. At present this company is running its mill on a custom basis, sampling and paying for the tungstic acid content according to a graduated scale of prices. On ore ranging from 1 per cent. to 30 per cent. WO_3 the price paid per ton increases with each per cent. tungstic acid contained, and above 30 per cent. WO_3 the price per pound of tungstic acid also increases with each additional per cent. This system of outright purchase of ore has superseded the former custom of milling the ore at a certain price and returning the concentrate recovered and is generally more satisfactory. It insures better work on the part of the mill and should make a better return to the miner.

At Cardinal, 2 miles west of Nederland, is the Cardinal mill of the Primos Chemical Company. This plant for the past eighteen months has been retreating the tailings made during four years' previous run, when the methods of saving were not as efficient as at present. The Lakewood mill of the Primos Chemical Company is located at Lakewood, about 2½ miles northeast of Nederland. It is the newest and most attractive of the mills in the district. The company's own ore is treated at present, although in the past a great deal of custom ore has been treated.

Between Cardinal and Nederland is the mill of the Eaton Mining & Milling Company, a small plant for company or custom work. On Beaver Creek, about 2 miles southeast of Nederland, are two small mills, one belonging to the Tungsten Mining & Milling Company, treating company ore, and the other owned by Smith & Ardourell, at present retreating the old tailings of the Wolf Tongue Mining Company. The Clarasdorf mill on lower Middle Boulder Creek is idle. In addition to the regular milling there is an effort in a small way to roughly concentrate some of the old mine dumps, either by screening and saving the fine mineral or by hang jigging. Any material obtained in this way is sold to the mills.

Difficulties of Concentration.

The concentration of tungsten ore presents difficulties not encountered with other base minerals. This is particularly true with some of the methods now in vogue. It is believed, however, that all of these obstacles can be largely overcome by applying principles and methods that have proved successful in dressing other ores. Excessive sliming is one difficulty, the cause of which is well set forth in the report of the State Geologist, previously mentioned.

"Ferberite is a rather soft mineral with one perfect cleavage, and generally one or more prominent partings. As a result the mineral is extremely friable even in the massive and massive-granular forms. Much of the ferberite was deposited as aggregates or loosely arranged crystals and crystal grains, forming crusts over the surfaces of rock fragments. One crust succeeded another until in many places the opening was filled. In other places the cavities remained open, but the walls were lined in the same manner. The crystal grains composing these crusts average not more than ⅛-inch in length and about 1/16-inch in diameter. In much of the ore where the crust is broken the crystal grains are easily separated from one another. When to this ready crumbling of the mass is added the extreme friability of the grains and crystals themselves it is easy to understand the excessive sliming. The finer parts of the slime form an almost impalpable mass which, when stirred in water, gives it an inky appearance, and the water remains turbid for ten days to two weeks. To save these slimes is one of the difficult problems with which the tungsten millman has to contend.

"Another serious problem is the successful treatment of the highly silicious ores. In almost all the tungsten mines there is a certain amount of highly silicious ore, consisting of minute grains of ferberite in a matrix of chalcedonic quartz or hornstone. The percentage of ferberite varies widely. Outside of certain limited areas this type of ore is fortunately not very abundant and rarely amounts to 20 per cent. of the product. Various methods of treatment have been tried, but none has given entirely satisfactory results. Even very fine crushing leaves a large part of the ferberite with particles of quartz attached. In concentrating, these grains consisting of quartz and ferberite will be disposed of according to their specific gravity. Those in which quartz is largely in excess will go with the tailings and ferberite will be lost, while those in which ferberite is abundant will go with the concentrates and help make a low-grade product."

Corroborative testimony on the difficulty of treating some of the ores is given by Mr. Victor G. Hills, who was connected with the Colorado Tungsten Corporation during 1905-7. This company treated custom ores, and at that time was doing the best work in the district. Careful records were kept and improvements were made wherever possible. From a list of twenty-one tests on custom lots the following are given as showing the extremes and average in percentage saving:

Lot.	Mine.	Crude Ore, % WO_3	Concentration ratio.	Concentrates.	Saving
4	D	8.07	8.69	62.17	88.90
3	C	6.07	181.81	40.37	5.03
15	E	9.51	8.93	62.59	75.11

In amount of tungstic acid in the crude ore Lot 3 compares favourably with average lots, but owing to its physical qualities it was a failure from a milling point of view. Mere assays would indicate that it was as good as any other ore, but milling tests proved its worthlessness.

The percentage of saving made in the Boulder County mills is largely a matter of conjecture in many instances. The smaller mills practise no regular control, and the larger concerns prefer to make no statement of their saving. Undoubtedly the efficiency is greater than it was four or five years ago, and as the best mill then operating made a customary saving of 75 per cent. to 85 per cent., it is probable that the claims of 90 per cent. saving may be realized in present practice. There is little loss in coarse tailing where that portion is allowed to go to waste, and the main loss is in the slime tailing. The statement is made that coarse tailing will assay as low as 0.1 per cent. WO_3 and that slime tailings from the best mills contain as little as 0.30 per cent. to 0.40 per cent. WO_3.

The mills are of small tonnage capacity. Four of them can treat about 5 tons in twenty-four hours, one of them 24 tons and another 40 tons in the same period. With two exceptions they are built especially for tungsten work and are new. The two old mills are remodelled gold mills, and while not as conveniently arranged as the newer plants, they are doing good work. A notable feature is the large table area required per ton of ore treated, which naturally reduces the tonnage capacity. In no instance is screen sizing being practised with a view to eliminating coarse material which might prove worthless. In view of the friable nature of the tungsten minerals it would seem that sizing should prove worthy of investigation, and certainly classification should be more widely practised.

The stamp is a time-honoured crushing device, and finds favour in some of the tungsten mills. Some of the considerations just given, however, indicate that the stamp is out of place in crushing tungsten ore. The minerals are friable and of high specific gravity. When crushed in stamps such material tends to slime excessively, both by reason of natural properties and the fact that it remains too long in the mortar. When this preliminary step has been taken it follows that elaborate provision must be made for saving fine mineral.

Another fact that indicates the wrong use of the stamp is that much of the mineral occurs in a condition which would permit of its liberation by coarse crushing. But, as a matter of fact, a screen analysis of table concentrates made from stamped ore will show about 60 per cent. passing a 150-mesh screen and almost 80 per cent. finer than 100 mesh. Modern ore-dressing practice would indicate some such method as follows on the average coarse-grained ore: Crushing by jaw crusher and rolls; screen sizing and jigging; regrinding jig tailing, with subsequent classification and table concentration; regrinding table middling, followed by slime concentration on belt machines, and, finally, treatment on canvas if found necessary. Screening might be combined with the classification in such a way as to eliminate a portion of coarse stuff carrying no value.

There is but one mill in the district that is successfully using the jig, and the results are satisfactory to the operators. Other plants are considering the use of coarse concentration, and a second mill will shortly go into commission on this basis.

There are, therefore, two distinct methods of treatment in vogue in the Boulder tungsten field. The first involves comparatively fine crushing with concentration on tables, vanners and canvas plant — the latter being a very important feature and extensive in area. The second includes stage crushing, jigging, concentration on tables and vanners, with a canvas plant as a minor adjunct. The adherents of each method claim an excellent saving, which is not questioned, but the advocates of stage crushing and coarse concentration claim a less expensive plant and cheaper operation. A further claim in favour of coarse crushing is that a greater percentage of high-grade concentrate is recovered, and, since the value of the concentrate is in direct proportion to its grade, it would seem rational to recover as much mineral of high grade as possible and reduce the percentage of fine or low grade concentrate.

But even with coarse crushing, and every effort made to reduce the quantity of slime, it is noticed that considerable fine mineral is produced which will float away, even from the boxes receiving coarse concentrates. One of the striking features of all the mills is the provision made for catching this fine floating mineral. Settling boxes of wood or cement are provided, and in one instance the water escaping from the settler passes through a cocoa matting filter. In this connection the idea suggests itself that the use of a coagulant might be beneficial. It is known that the tungsten concentrate will not settle perfectly clear for several days. The simple expedient of adding a small quantity of lime water will show how quickly the solution will be clarified. On a laboratory scale the mineral thus treated will settle and leave a clear solution in a few minutes. Experiments on a large scale might show that the addition of lime solution at the time of fine grinding would be beneficial in coagulating the mineral and aiding in its recovery. Or, the addition of clear lime water to the concentrate settling boxes might prevent the loss of fine and floating mineral after it had been separated from the gangue. Other salts than lime, which are of proved value in coagulating colloid mater, might be experimented with to advantage.

Magnetic separation has been applied successfully to tungsten ores, but it is not in vogue in the Boulder field. The Boulder ores are remarkably free from sulphides of iron, lead and zinc, cassiterite, arsenopyrite, etc., which usually call for magnetic separation, and this probably accounts for the non-use of expensive magnetic treatment.

Granby's Hidden Creek Copper Mine

As has already been announced, the Granby Consolidated Mining, Smelting & Power Company, Limited, has decided to complete the purchase of the Hidden Creek copper mine, situated near Goose Bay, Observatory Inlet, British Columbia. At the meeting of directors of the company held last month in New York to determine the course to be taken, payment of half the price of the four-fifths interest, due June 1, was authorized, bringing payments on account up to $215,000, and leaving $185,000 to be paid next December to clear the property of liability on this account. In addition, a sum of $200,000 was appropriated for more development work and necessary plant and in

vements. Further, the purchase of Mr. M. K. lgers' one-fifth interest was arranged for, so that whole interest in the property will be owned by the Granby Company after the final payment shall be de next December, or earlier if deemed desirable.

From Mr. Jay P. Graves, vice-president and general nager, it was learned recently that the reports of engineers were before the board of directors, when matter of purchase of the property was being fily considered. The estimates of available ore, compted from results of development work done on the perty and cores from diamond drill holes, varied m a minimum of 6,000,000 to a maximum of 12,-0,000 tons.

In regard to the appropriation for development work improvements, above mentioned, Mr. R. M. Sylster, assistant to the general manager; Mr. O. B. ith, Jr., superintendent of the company's mines, Mr. H. J. C. McDonald, one of the company's min engineers, have gone to Goose Bay to arrange for energetic prosecution of the work to be done above ound, so that full advantage may be taken of the e weather for surface operations; also to decide at new development shall be undertaken.

Mr. W. Yolen Williams, who has from the inception the Granby Company's Boundary district mining terprise been associated with Mr. Graves, is to at ce make Vancouver B.C., his headquarters with the ject of gathering exhaustive information relative to pper mining and smelting in the Coast district, so at, before determining upon the course to be adopted connection with the reduction of the Hidden Creek ne ores, the relative advantages of having them elted at one of the existing custom smelteries and establishing its own smeltery on the Coast, may be lly before the management of the company.

The events of the last few months have, therefore, veloped in a manner so satisfactory to the directors the Granby Company as to have influenced them to mmitting the company to what will without doubt ove its permanent operations on the Coast of an imrtant mining and smelting industry.

The Porcupine Fire.

Just as we are going to press news arrives that many orcupine mining camps have been utterly destroyed y forest fires. Word also arrives of the deaths of Veiss and Moore, both well known in mining circles.

So far there is no information as to many Toronto en who were in Porcupine.

It is possible, though not probable, that fully five hunred lives have been lost. The chances are that not nore than one hundred lives have been offered as sacrices to the monumental stupidity that made the disaster ossible. This moral stands out: We must absolutely pend money in safeguarding our forests before we can efer to them as assets.

We have dwelt upon commercial aspects designedly. But there is another view. Many brave men have lost heir lives in Porcupine. The history of the Porcupine ire will never be written adequately. There is no doubt hat an amazing amount of bravery was manifested throughout the whole sad episode. Men like Billy Moore lost their lives willingly in attempting to save others. It is one of the traditions of mining camps that men must be brave. Porcupine, from all accounts, lived up to that tradition.

It is necessary for all of us to put our cheque-books at the disposal of the Porcupine sufferers. The next few weeks will witness the keenest suffering. If we can do anything to alleviate that suffering, we must do it now.

We have made arrangements with the Imperial Bank of Canada whereby any branch of that institution will receive and transmit donations to the relief fund. The formal name of the fund is the Canadian Mining Journal Fire Relief Fund. It is especially desired that all mining men become identified with the movement.

Remittances may be sent to any branch of the Imperial Bank, or to this office. A full list of subscribers will be published in an early number of the CANADIAN MINING JOURNAL.

* * * *

The latest news at date of writing places the list of deaths at 87. This is by no means complete. Many of the survivors have suffered horribly. Whilst the loss of property has been severe, it is by no means as large as was at first believed. It is immensely distressing to know that the whole tragedy could have been prevented. Early precautions on the part of mine owners would have insured the immunity from fire of individual plants. An adequate system of fire-ranging would have limited the fire-swept zone.

Two facts are to be remembered. The same kind of holocaust may easily occur again. It is essential that advantage be taken of the experience of men who know the bush. Mining men from other countries rarely realize the urgent need of adopting preventive measures.

Upon the mining population itself and upon the Ontario Government rests the responsibility of acting at once and of continuing to act.

SILVERTON MINES, LIMITED.

The Silverton Mines, Limited, owns the Hewitt-Lorna Doone group, situated three or four miles from Silverton, Slocan Lake, B.C. Much development work has been done on this group during several years, under the direction of Mr. G. Stilwell. The following is an outline of what is now being done and what it is intended to do in the near future:

Mine.—Development work only is in progress. The ore taken out in the course of this work is hand-sorted and the high-grade sorted ore is shipped to the smeltery.

In earlier years several tunnels were driven from the western side of the mountain. Of late years all work has been done from the eastern side, on which a new camp was established to facilitate this development.

No. 4 tunnel has been connected with the work from the western side. Three orebodies have been opened

on this level; these are 115 to 155 feet in length and average 7 feet in width. Raises in these orebodies have been put through to No. 3.

The face of No. 6 tunnel is within about 200 feet of that of the drive from the west on the same level. When connection shall be made, this tunnel will be rather more than 3,000 feet in length through the mountain. Orebodies have been passed through, but only one has been proved up to No. 4.

No. 7 tunnel is 135 feet below No. 6; it has been driven about 700 feet, developing orebodies containing ore as good as any taken from other parts of the mine, for much ruby silver and grey copper occur in this ore.

Mill.—The company has the Wakefield concentrating mill, situated on Four-mile Creek. The equipment has been overhauled and the water supply ditch and flume repaired, ready for the season's run, but operations will not be commenced until about the middle of June, by which time, it is expected, one unit of the more Vacuum Process plant will have been instal the machinery, etc., for this having already been ceived at the mill. This plant will be used, in con tion with water concentration, to re-treat the mc middlings. Hewitt-Lorna Doone ores contain a la quantity of siderite, to deal with which the Elm plant has been obtained, and it is confidently expe that a zinc product, containing 45 per cent. or more zinc and 100 ounces of silver per ton, will be ma About 100 tons of ore will be put through the daily, but the higher-grade ore will be first sor out for shipping crude to the smeltery.

The mines of the Silverton Mines, Limited, have so much development work done in them, and so c siderable a quantity of ore is blocked out ready stoping, that a long mill run is looked forward to, profitable results are confidently expected.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Dominion Coal Outputs.

The outputs for June will total 365,000 tons, thus exceeding the best previous record for this month, namely, 358,069 tons in June, 1910. The aggregate outputs for the first half of the year during the past four years compare as follows:

1908	1,931,400
1909	1,628,161
1910	1,554,986
1911	1,889,539

New construction is now well under way around the mines. No. 14 colliery is about complete with the exception of the permanent hoisting engine. The output increased rapidly during the month and is now averaging between 700 and 800 tons per day. The new bankhead is working smoothly and with a remarkable economy of labour. The new compressor house at this colliery is as nice a colliery building as one need wish to see. The house is built of the slag-cement brick manufactured at Sydney, and is large and lofty. The compressor is electrically operated, taking current at 6,600 volts. It is built by the Canadian Rand Company, and consists of an alternating current motor of 600 horse power, and compressors with a capacity of 3,000 cubic feet per minute. The absence of heat and noise is very marked, and with the new clean and airy building this compressor-house marks a distinct advance. All the machinery with the exception of the temporary hoisting engine is run by electric power, including the bankhead and screening plant, the ventilating fan, lamphouse, etc., and as a result No. 14 is a remarkably clean and quiet colliery. The growing importance of the Lingan collieries may be gauged by the fact that it has been found necessary to install a telephone central to serve this district.

The tracks for the new pier at Sydney are under construction, and the sub-structure of the pier is being erected. Creosoted piles are being used, the creosoting being done at the neighbouring works of the Dominion Tar & Chemical Company. This is an instance of the self-contained character of the industries which are growing up around the Steel and Coal works. As previously mentioned, considerable use is being made of the slag-cement bricks of the Sydney Cement Company, which are made from the Steel Company's slag. In the same way the Tar & Chemical Company disposes of many of its manufactured products to the mines and works of the Steel Corporation, these being in their turn by-products of the main industries. Even the new houses which the Coal Company is building in such large numbers at Lingan are lined with tar-paper made in Sydney from one of the by-prod of the coke-ovens. The slag-fertilizer plant now under c struction in Sydney will add one other to the subsidiary dustries, and the product will doubtless find a ready local s

Editor's Note.—For comment upon the flooding of the P Hood-Richmond colliery, see editorial pages.

ONTARIO.

Cobalt and Gowganda.

The Buffalo mill report for May shows mill ran 615 hou ore treated, 3,335 tons; average assay before milling, 37 ounces; ounces recovered, 104,255; expenses, $4,925.

A new vein showing some leaf silver has been cut at t 300-foot level of the Ophir Cobalt shaft. The lead is wi but values are not very high so far.

With the 10 per cent. dividend cheque sent to McKinl Darragh-Savage shareholders, the following statement was s mitted: cash on hand, $383,024; ore at smelters, $115,600; at mine ready to ship, $38,500; total, $537,124, surplus June 15. For the first six months of the year there has be produced 1,300,000 ounces, at a cost of about the same as la year, or 17.50 cents per ounce.

The Kerry lease on Peterson Lake is getting some cob and silver shot rock from a winze sunk on its vein at the 12 foot level. The vein has been cut at the 200-foot level a here it shows silver.

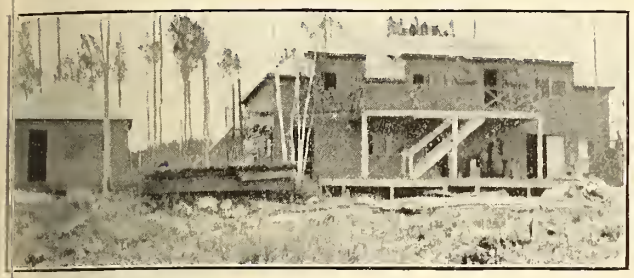
At the 150-foot level on their Peterson Lake lease the No Scotia Company has opened up 40 feet of ore. The vein from two to three inches wide and the wall rock for son distance will make good milling rock.

Before next month Mr. J. T. Englehart, chairman of t T. & N. O. Commission, will visit Elk Lake and Gowgand with a view to ascertaining the prospects for a railroad.

Porcupine and Swastika.

In the last week three excellent surface discoveries hav been made at the Swastika camp and there is now certai to be a centre of activity at this little station on the T. N. O. for some years. The Swastika mine was staked in 190 and has been worked for the last four years. The surfac discoveries at the Swastika were not nearly as spectacular a any of the three that have recently been made to the nort of the railroad. At the 100-foot level of the Swastika ther is an ore body 120 feet long and the bottom of the winz sunk to the 200-foot level shows quartz much richer than a any other point or level in the mine. A small stamp mill i operating, and until further development has been undertake

further addition will be made to it, though a 9-drill compressor has been ordered. The three finds which have attracted most attention to date are to the north of the track, which here runs east and west. Two of them are on the Hurd properties and one on the Miller, and all are promising. Other



Swastika Mining Co., Office and Store.

properties in this section with good leads are the Porcupine Swastika, the Homestead mines of Swastika, and the Reeves. A siding has just been completed, an hotel has been opened, and a little settlement is growing up near the tracks at a point about 25 miles north of Englehart.

A discovery has been made on the John Brydge claim in Bristol Township which has caused a great stampede and the staking of every acre of land and water within miles. The original discovery is described as meritorious, by witnesses competent to judge, a wide ore body showing free gold plentifully. The trail in is easily accomplished. A gasoline will carry all equipment down to Redsucker Creek on the Mattagami, when there is but one portage and a walk of two miles to the find. The owners are asking $5,000,000 for the claim.

The T. & N. O. Commission, accompanied by the Hon. Frank Cochrane, officially opened the Porcupine Railroad on Dominion

Outcrop on Martin Group. Swastika Region.

Swastika Region, No. 1 Vein Martin Group.

Day, and on July 3rd the regular service went into operation. Train arrives in Porcupine at ten o'clock at night, and leaves at 5.30 in the morning. Freight is taken into the Dome road. The extension of the steel to the Hollinger is promised for the first day of October, and already the right of way has been cut. To serve the needs of the Pearl Lake section two or three townsites have already been planned, one by the Timmins-McMartin-Dunlap syndicate on the Campbell veteran, another on the Schumacher veteran, and another on the Mattagami River itself. There has been a lumber famine in Porcupine, but now that freight can be brought in, buildings are going up with great rapidity. The census showed that there were 1,500 people living in the settlements round the lake and there are at least 3,000 men working in the mines and prospects of Tisdale and Whitney, so that it would be safe to estimate the present population in the district at between 6,000 and 7,000.

Fire again swept through Tisdale Township, but the only serious loss was at the Dome Extension, where everything was destroyed. Pearl Lake, the Jupiter, and camp 1 of Bewick-Moreing & Company, had very narrow escapes, and many isolated prospectors lost their tents and supplies.

Some very remarkable showings have been made on the McIntyre property on Pearl Lake in the last two weeks, both on the surface and underground. Some of the richest samples

yet encountered have been taken off the surface, and at the 100-foot level a drift on one vein shows free gold in both faces. The ore from a shot drill at 253 feet also shows gold. Two other shafts have been sunk on the property. A 12-drill compressor plant has been ordered.

On a claim just south of the Rea mines, the Armstrong-Booth has just uncovered a new vein which has yielded some very rich samples and pans remarkably. So rich is the dirt that a rocker has been installed and the dirt is being washed. The lead is about four feet wide of quartz and schist.

At the 200-foot level, while drifting on its vein, the Rea Mines has just run into ore as spectacular as the surface, where the vein was very rich and four feet wide.

Some rich specimens of quartz have been taken out of small stringers on the La Palme syndicate's property in northeast Whitney.

One of the veins on the Imperial Porcupine was cut at the 100-foot level this month. The vein shows gold. Some remarkable surface finds have been made on the Dome Extension, and both with diamond drill and in the shaft exploration work at the North Dome has been successful.

The fire at the Hollinger laid bare some very spectacular quartz stringers. Plans at this property are being very carefully laid before the reconstruction of the camp commences.

At a distance of 160 feet from the shaft the Foley-O'Brian cut into its vein, and it is said to be better than was anticipated by the owners. Mr. Harold Rickard, brother of Mr. T. A. Rickard, has now taken charge of the property in succession to Mr. A. F. Motz, who will open up the Shillington-Richardson claim near the Hollinger.

The American Goldfields Company, controlled by the Steindlers of New York, has decided to sink a shaft on its Tisdale property near the West Dome. Two shot drills have been working on the claims until now.

Despite reassuring rumours there has been no conciliation between the Pell and West Dome interests, who own a half share each in the big Curts vein on Edwards Lake. The West Dome Mining Company was offered the other half share at a certain price, which it refused to give, and the whole claim will now be auctioned to the highest bidder in the open market.

BRITISH COLUMBIA.

Mr. E. Jacobs, of Victoria, recently spent seven weeks in parts of West Kootenay, Boundary, and Similkameen districts. Of mining in the several districts he visited, he speaks hopefully. Much important development work is being done, and in several parts production is on a comparatively large scale with, in some instances, profitable results. Agricultural and horticultural matters were also found to be progressive in some of the parts in which time was spent, notably in the vicinity of Grand Forks and Keremeos, respectively.

Mr. Jacobs left Victoria for Kootenay on May 8 to attend a meeting of the Western Branch of the Canadian Mining Institute, convened to be held at Trail on May 18. Before proceeding to Trail, he spent several days obtaining information relative to progress at silver-lead mines and concentrating mills near New Denver and Silverton, Slocan Lake. He paid his third visit in eighteen months to the Standard mine, above Four-mile Creek, now being operated by the Spokane company organized early this year to acquire and work it. He was shown the face of No. 5 tunnel, a cross-cut at which had then opened about 85 feet of concentrating ore, in which occurred a fair proportion of clean ore suitable for shipping crude to the smeltery. At Spokane he was afterwards informed that the cross-cut had since proved the ore shoot to be 131 feet wide in this part of the mine. The work of constructing an aerial tramway from the mine to the mill site near the lake, of putting in a water supply system, and erecting a 100-ton concentrating mill, was being energetically proceeded with, the expectation being that all will be in working order during the ensuing fall.

The Van Roi mill, at which operations were commenced about the middle of March, was doing good concentrating work, making two marketable products, namely, silver-lead and silver-zinc concentrates. Mr. Douglas Lay, superintendent, expressed confidence that both mine and mill are in such a working condition that a long and profitable run may reasonably be expected. From Mr. G. Stilwell, manager of the Silverton Mines, Ltd., which has for years been opening the Hewitt-Lorna Doone mine, it was ascertained that the company has large reserves of ore available for extraction, and that during June, after installation of one unit of the Elvacuum process plant which is to be used for treating "middlings," the Wakefield mill would be running on ore from this mine.

At Trail, the meeting of the Canadian Mining Institute was well attended and a number of interesting papers on mining subjects were read and discussed. The provincial mineralogist, Mr. W. Fleet Robertson, of Victoria, the retiring chairman of the branch, presided until after announcement of the result of a ballot, which made Mr. Robert R. Hedley, of Vancouver, his successor, and the latter thereupon took the chair. Visits were paid to the Consolidated Mining & Smelting Company's big lead and copper reduction works at Trail, and the Centre Star group of mines at Rossland, all of which were found to be in a flourishing condition, with new and modern plant being put in at the former, and much ore of good grade opened in the latter.

In the Boundary district, the Granby Company was not operating its big smelting works at the time Mr. Jacobs was at Grand Forks, but coke had been ordered from Pennsylvania in order to admit of most of the blast furnaces being blown in again. Meanwhile the works needed repairs and renewals were being made, and plans for important betterments were being advanced. It was gratifying to have assurance that a considerable quantity of ore of higher grade than the average of recent years was being mined by the Granby Company at Phoenix. Later, at Spokane, Mr. Jacobs was informed by Mr. Jay P. Graves, general manager of the company, of the arrangements made by the directors in New York to complete and extensively work the Hidden Creek copper mine, on Observatory Inlet.

The British Columbia Copper Company was found to be using Pennsylvania coke at its smeltery at Greenwood, and acting general manager, Mr. E. G. Warren, gave the visitor particulars of the company's operations at its several mines in the Boundary district, and across the International boundary line in the neighbouring State of Washington. The company's Lone Star and Washington mines were visited, the trip over the intervening high mountains having been made in the company's automobile. From this mine to the C. P. R. Columbia & Western Railway at Boundary Falls, a well-constructed aerial tramway, five and a half miles in length, is now in use. The same company's Wellington camp group, also known as the Jackpot, was visited, and the big occurrence of oxidized ore seen.

Two other items of Greenwood intelligence will be noted—one, that some rich silver-gold ore is being taken out of the old Elkhorn mine, and the other that the Greenwood-Phoenix Tramway Company's big tunnel early in June was in 2,000 feet, with the expectation that 300 to 400 feet more driving will result in one of the ore veins of the Reliance claim being cut.

At Hedley, a day was spent, chiefly in examining the new stamp mill and cyanidation plant of the Hedley Gold Mining Company, to which important additions have been made during the last twelve months, with decidedly satisfactory results. The tonnage of ore milled and treated is now much larger than

lier, and the company is earning comparatively large profits, is manifest when it is seen that it has distributed already year $120,000 in dividends paid to its stockholders, this ng 10 per cent. on the issued capital.

Around Princeton, several of the coal mines that are being oned were visited; as also was the site of the British Columbia Cement Company's cement manufacturing works, the buildings for which are in course of erection. The Princeton Coal & Land Company, an auxiliary organization of the Vermilion Forks Mining & Development Company (owning the Princeton townsite and various mining properties in the vicinity), has made most progress towards development of coal mining, its mine in the immediate vicinity of the town having nearly a dozen working faces opened, with more that can be opened whenever there shall be a demand for the coal. The chief drawback to this company's material progress is the lack of plant and machinery for sizing and cleaning the coal. After these shall have been provided, a prosperous coal-mining industry will, no doubt, be established here. Among other properties worthy of mention are those of the Osoyoos Coal Company of Nelson, which has fully 60 feet in thickness of coal in a prospecting adit; the Princeton Collieries, Ltd., of Vancouver, and the Columbia Coal & Coke Company, of Winnipeg, which last is actively engaged in developing coal seams that have been opened from both Collins Gulch and Granite Creek sides of the basin in which they occur.

An important transaction now in course of negotiation is that for the purchase of the Voigt properties—copper claims, coal lands, timber lands, water rights, etc.—on Copper Mountain, situated a few miles from Princeton. Particulars of these properties will shortly be published; meanwhile Mr. Emil E. Voigt is in Spokane, continuing negotiations with representatives of the Boston and New York men who have made offers for the purchase of the property. The development of the mineral resources of Copper Mountain, with the necessary accompaniment of the establishment of a copper smeltery, would do much to advance the material interests of this part of the big Similkameen country.

Two days were occupied in visiting Tulameen, where Mr. Jacobs had the advantage of much conversation with Mr. Chas. Camsell, of the Canada Geological Survey. Mr. Camsell has spent five or six field-work seasons in the Similkameen, so is especially well informed concerning its geology and mineral resources. The Survey party was arranging to wash Tulameen gravels to try to find diamonds in the wash, it being thought probable that as diamonds are known to occur in the solid rock of the vicinity, there may be some found in the river gravels.

Mr. Jacobs returned to Princeton, and thence to Spokane, Seattle, and Vancouver, by rail. Among others seen in Spokane was the managing director of the Corbin Coal & Coke Company, which has during the last three years been working a coal mine in the Crow's Nest district, southeast Kootenay, and which has opened one of the most remarkable deposits of coal known to occur in the West. The proportions of this deposit are so large that the incredulity of those who are without opportunity to satisfy themselves of the statements concerning them is aroused; nevertheless it is a simple fact that there is on the Corbin Company's coal property a body of bituminous coal of phenomenal size, from which millions of tons can be easily extracted, and, too, of excellent average quality.

In Seattle, information was obtained relative to the work of the Geological Survey of the State of Washington, of the progress of the coal mining of that state, and concerning the work of the United States Geological Survey's mine-rescue training work, in connection with which about 20 men have already been trained and proved competent for rendering aid in case of emergency. Mr. Jacobs has returned to his headquarters in Victoria to there prepare for publication in detail much of the mass of information gathered by him during his trip.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—Advices from Port Hood state that the water is still rising rapidly in the mine, and that only the choking of the fissure can save the mine from being flooded to the high water mark.

Yesterday the water had risen to within 262 feet of the low level in No. 3 lift, and was rising vertically at the rate of one inch in seven minutes. The water will continue to rise at this rate for some days, and will reach the low level in No. 2 lift within five and one-half days.

The only hope to save the mine is for the fissure to become choked, otherwise the water will rise to the high water sea level, which is about 500 feet above No. 3 low level.

Glace Bay.—The construction of the Dominion Coal Company's new line of railway from Morien Junction to Birch Grove, the company's new colliery, No. 20, was started to-day. The line, which will be about four miles long, will be constructed by the company's own men. The development of this new mine will be rapid after the new railway is completed, and already the company is preparing to sink a new slope which will be started this week, and will be about 2,000 feet south of the present one. The coal at this mine is of the best quality, and it is expected that operations will be far enough advanced to begin the shipment of coal before the close of navigation.

ONTARIO.

Toronto.—After about a dozen postponements, the assets of the Standard Cobalt Mines, the old Cobalt Central, were sold by E. R. C. Clarkson to Philadelphia interests for $100,001. There was a reserve bid of $100,000, which was exceeded by $1.

Ottawa.—His Excellency the Governor-General in Council has ordered that the regulations for the disposal of quartz mining claims established by order-in-council of the 13th August, 1908, with the restriction of a subsequent order-in-council of the 16th February, 1909 extending such regulations to the reserves set apart by the Dominion Forest Reserve Act, be extended, and made applicable to lands within forest reserves and parks established by the Dominion Forest Reserves and Parks Act, of 1911, with the exception of Elk Park, within the Cooking Lake forest reserve, and the Buffalo Park reserve in the Province of Alberta.

Whereas, under the provisions of the Forest Reserves and Parks Act, 1911, all regulations with respect to the Canadian national parks have been rescinded, his Excellency in-council has been pleased to order that the regulations provided for in the following orders-in-council shall be re-established and made to apply to all Dominion parks proclaimed under the Forest Reserves and Parks Act:

1. The regulations of the national parks of Canada, approved 21st June, 1909.

2. Amendments to the above regulations approved September 26, 1910.

3. Regulations for the use of motor vehicles in the Rocky Mountain park, approved April 8, 1911.

4. Regulations for the management and control of the Dominion Government water and sewer systems and of plumbing and sanitation at Banff, approved June 23rd, 1908.

5. Amendments for the above water, sewer, and plumbing regulations approved March 10, 1909.

6. Regulations for the administration of timber within the Rocky Mountains, Yoho, and Glacier Parks, approved May 21, 1906.

7. Amendments to the above timber regulations approved February 15, 1911.

8. His Excelleney the Governor-General-in-Council has also ordered that the regulations established on the 20th April, 1910, for the leasing of Dominion lands for coal mining purposes, with the restrictions of the subsequent order-in council of February 28, 1911, shall be extended and made applicable to lands within forest reserves and parks established by the Dominion Forest Reserves and Parks Act of this year with the exeeption of Elk Park and the Buffalo Park reserve. A similar order-in-council has just been passed with reference to the leasing and use of lands containing limestone, granite, slate, marble, gypsum, marl, gravel, sand, or building stone. No lease for quarrying purposes shall be granted without the approval of the superintendent of the park or unless he is satisfied that the granting of such lease will not mar the beauty or the utility of the park or unduly interfere with the purposes for which it is established.

Still another order-in-council recently adopted at Ottawa provides that the waterpower regulations pursuant to the Lands Aet, 1908, and amendments, shall be held applicable to all Dominion forest reserves and parks.

Cobalt. — The Cobalt dividends to be disbursed during July are estimated at $1,785,000.

Cobalt.—In a crosscut from the 100-foot level of the No. 123 shaft of the Nipissing an excellent vein of high-grade ore has been eut. This is an entirely new lead and was picked up 150 feet east from the shaft near the O'Brien line. Another vein which did not make ore, was sunk upon, and this is the first tangible result of development near the O'Brien and Chambers-Ferland line in the Keewatin formation. No. 12 shaft of the same property has also been pumped out and some very pretty ore is being mined here.

Porcupine.—A private despatch from Porcupine states that about August 1st the Dome mine will start 20 stamps, and will begin the shipments of gold bars.

Toronto, July 5.—A suit has been instituted against the Kerr Lake Mining Company by the Hargraves Silver Mines, Limited, for the recovery of $150,000, being the valuation of the ores which the plaintiffs claim were taken out of a vein running into their property and at a point outside the boundaries of the Kerr Lake mine.

It is reported the Kerr Lake Company has offered to settle the claim by the payment of $25,000, but that the offer has been refused by the plaintiffs, who will carry the case through the courts.

BRITISH COLUMBIA.

Nelson, B.C., July 1.—With the object in view of the establishment of a school of mining for the Kootenay, the Nelson Board of Trade is in correspondence with the various institutions of learning and scientific institutions in Canada and the United States, respecting modes of organizing a school of this character, and the probable cost of creation and maintenance. The model that is favoured is that of the School of Mines at Sudbury, Ont., which is conducted as a special department of the Sudbury High School, and is the child jointly of the Sudbury School Board, the mining men of the district and the Ontario Government. This city has reached the stage where a new high school building is required, and after the summer term there will be four instructors on the staff. For some time fourth year work has been done by the Nelson High School, admitting its matriculants to the second year of McGill and Toronto Universities, and a department of mining, under a mining instructor, is therefore in line.

Vancouver.—The Inland Coal & Coke Company, Limited, capitalized at $1,500,000, with head offices in Vancouver, has been formed for the purpose of taking over the holdings of the Coal Hill Syndicate, southwest of the Nicola Valley Coal & Coke Company's Middlesboro properties. Joseph Graham, general manager of the Coal Hill Syndicate, is the general manager of the new corporation.

Mr. G. I. Wilson, of Vancouver, who was one of the principals in the Coal Hill Syndicate, and who has been interested in other properties in the Nicola coalfields, is the president of the new company; and W. L. Nicol, who was also interested in the Coal Hill Syndicate, is the vice-president.

It is the intention of the company to double the present output immediately. This is made possible by the development work already completed.

COMPANY NOTES

BUFFALO ANNUAL FOR 1910.

During the year the mill treated 41,484 tons, averaging 36.07 ounces of silver per ton, or 1,496,255 ounces, of which 80.07 per cent. was recovered as follows: 25,795 ounees in metallies, 540,078 ounces in jig concentrates, and 632,202 ounces in table eoneentrates, or a total of 1,198,075 ounces recovered, or 1,098 tons of concentrates, averaging 1,067 ounces per ton, and 1,880 pounds of bullion.

The cyanide plant treated during the year 11,700 tons of slime from the concentrator, averaging 13.06 ounces of silver per ton, or 152,783 ounces, of which 67.62 per cent. was recovered, or 103,321 ounces. The total recovery by mill and cyanide was 1,301,396 ounces, or 86.98 per cent.

The shipments during the year consisted of forty-five cars of ore, containing 1,079 tons of eoneentrates from the mill and 126½ tons of high-grade ore direct from the mine, or a total of 1,205½ tons of ore and concentrates shipped. There were also several small sales of native silver. The returns from these shipments and sales amounted to 1,392,700 ounces, of which approximately 279,852 ounees were contained in the ore and 1,112,848 ounces in the concentrates, or an average of 2,221 ounces per ton in the ore and an average of 1,031 ounces per ton in the eoncentrates. In addition to this there were shipped 9,170 pounds of bullion, the smelter returns from which amounted to 114,419 ounces.

Besides the shipments made there was on hand at the mine at the time the report was sent out 11,054 pounds of concentrates, containing 11,772 ounces, also 27,435 pounds of table concentrates, containing 11,276 ounces, and 837 pounds of bullion, containing 10,815 ounces, or a total of 33,863 ounces on hand.

During the year the ore reserves were increased by approximately 36,000 tons, or the equivalent of 1,118,000 ounces over that shown at the beginning of the year, which is a slight increase over the extraction for the previous year. This was principally on No. 10 vein. There is a decrease in stock piles on the surface of 7,779 tons, and an increase of broken in the mine ready for milling of 3,045 tons, making a total of ore broken in stopes ready for milling of 23,334 tons, in addition to the stock piles on the surface.

During the year the tonnage was broken as follows in the mine: In sinking, raising, and station cutting, 1,287 tons; in drilling, 4,942 tons; and in stoping, 30,521 tons, making a total of 26,750 tons of milling ore broken, of which 33,705 tons were hoisted and 3,055 tons left in the mine. In addition to the 33,705 tons hoisted from last year's tonnage, there were hoisted 7,779 tons from stock piles on the surface, making a total of 41,484 tons hoisted, all of which went to the mill.

Work Accomplished.

The total drifting during the year amounted to 1,412 fe

king, 44 feet; raising, 73 feet; station cutting, 54 feet; and ping, 53,321 square yards for the year. The totals to date lude 977 feet of shafts, 9,028 feet of drifts and 895,260 c feet of stoping done in the mine.

STEEL COMPANY DIVIDEND.

e Steel Company of Canada has declared the regular quar- dividend of 1¾ per cent. on the preferred stock, payable ust 1, to shareholders of record July 22.

MOND NICKEL.

ond Nickel Company is about to issue £250,000 5 per cent. mortgage debentures at par for the new enlarged smelt- works at Coniston, Ontario, and other purposes.

CANADIAN COAL & COKE COMPANY.

he shareholders of the Pacific Pass Coal Fields, at a special eral meeting, ratified the by-law passed by the directors acquiring securities of the Canadian Coal & Coke Company, for selling to that company securities of Pacific Pass Coal ds.

The question of the consolidation in the Canadian Coal & Coke Company, Limited, of the control of the large coal properties in the west at Lethbridge, Pincher, Edmonton, and Yellowhead Pass, on the G. T. P., was fully considered and discussed.

The meeting, by a majority of more than two-thirds of all the shares represented, confirmed the by-law, thus approving the consolidation as in the best interests of all parties concerned.

The consolidated companies will control four of the finest coal properties in Western Canada, developed and equipped under the direct supervision of Mr. Charles Fergie, M.E., an engineer of experience and high standing.

The combined capacity of the mines will be about equal to that of the Dominion Coal Company, and their location will permit of the western market being supplied with the shortest haul.

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

llowing are the shipments from the Cobalt camp for the k ending June 30, and those from Jan. 1, 1911, to date:

	June 30. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger		55,200
Bailey		40,000
Barber		6,000
Beaver	62,500	779,208
Buffalo		1,405,860
Chambers-Ferland	64,000	703,000
City of Cobalt		557,980
Cobalt Lake	145,760	2,269,450
Cobalt Townsite		480,700
Colonial		88,000
Coniagas	58,030	2,112,210
Crown Reserve		1,275,420
Hargraves		161,100
Hudson Bay		585,960
Kerr Lake	60,050	1,382,090
King Edward		40,000
La Rose	130,344	3,184,570
McKinley-Dar-Sav.	174,575	3,163,605
Nipissing	306,247	3,330,107
O'Brien		673,040
Peterson Lake (Little Nip.)		58,430
Provincial		40,510
Right-of-Way	63,388	642,948
Silver Cliff		106,680
Standard		102,813
Temiskaming		860,852
Trethewey		672,380
Wettlaufer		117,232

e shipments for the week were 1,064,894 pounds, or 532 tor

e shipments from Jan. 1 to June 30 were 24,875,349 po ds, or 12,437 tons.

llowing are the shipments from the Cobalt camp for the we ending July 7, and those from Jan. 1, 1911, to date:

	July 7. Ore in lbs.	Since Jan. 1. Ore in lbs.
Badger		55,200
Bailey		40,000

The shipments for the week were 603,154 pounds, or 301 tons.

The shipments from Jan. 1 to July 7 were 25,478,503 pounds, or 12,739 tons.

Following are the figures of German consumption of foreign copper for the months January to May, 1911:

Imports of copper	tons	74,313
Exports of copper	tons	3,211
Consumption	tons	71,102

as compared with consumption during the same period in 1910 of 66,388 tons.

Of the above quantity 64,555 tons were imported from the United States.

B. C. ORE SHIPMENTS.

The ore shipments for the week ending July 1 were 39,044 tons, and the tonnage smelted was 36,835. The following is the record to date:

Nissen Stamp Mill

The Nissen Stamp Mil

STAMP. The Nissen Stamp drops with great crushing effect up a feed comparatively free of the fines caused by preceding impac This causes an actual splash which radiates from the centre of the d carrying the pulp to a circular screen, every aperture in which prese a full opening for the pulp which has already reached size to p through. As the stamp ascends preparatory for the succeeding blow, partial vacuum is formed under stamp shoe, which greatly assists the rapid return of the oversize to the die. The condition, the circular form of mortar, and the ascending stamp; lead to a suction effect which hastens the return of oversize to the die, a feature distinctive to the Nissen Stamp. Thus, a greater number of effective drops per minute is possible, resulting in greater capacity.

FEEDER. Each Nissen Stamp is provided with a tappet driven, automatic ore feeder of the Challenge type. This feeder is easily adjusted for different rates of feed, and is very sensitive in responding to the action of the stamp.

MORTAR. The Nissen Mortar is circular in plan and made to accommodate but one stamp, thus confining the crushing zone to a field of activity which forbids pulp coming to rest or becoming sluggish in that circulatory movement essential to efficiency.

Boston Consolidated type "B" Nissen Mortar.

The screen of the Nissen Mortar is circular and extends more than half way around the mortar, forming an area of discharge for one Nissen Stamp equal to about two-thirds that employed for five stamps of the old type.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

DEPARTMENT OF MINES. GEOLOGICAL SURVEY.

PUBLICATIONS

The Geological Survey has published maps and reports dealing w h a large part of Canada, with many local areas and special subje s.

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired wi be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the precise area n- cerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for w ch it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mi ng Institute, etc.

NOTE.—Maps published within the last two years may be had, printed on linen for field use. A charge of cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and econom geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature r ported upon. Letters and samples that are of a Departmental nature, addressed to the Director may be mailed O.H.M.S. free of postag

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

BRITISH COLUMBIA

The Mineral Province of Canada

as produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; 17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; r a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 he Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

A MESSAGE

TO

MINE SUPERINTENDENTS

WHO HAVE

IDEAS OF THEIR OWN

We will build your Skips, Ore-cars, Sinking Buckets, etc., to your own drawings, and exactly as you want them, or we will submit drawings for your approval.

DON'T let anybody force **CHEAP STOCK CARS** on you, when you can get them built as you know they ought to be.

You will find our cars in every Mining Camp in the North.

We are also prepared to furnish Tube Mill Liners. Chilled Wheels and Castings of all descriptions.

THE
SUDBURY CONSTRUCTION & MACHINERY CO.
LIMITED
SUDBURY :: ONTARIO

Province of Quebec

Department of Colonization, Mines, and Fisheries.

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. T price of this certificate is $10.00 and it is valid until the first of January following. This certificate gives the right to prospect public lands and on private lands, on which the mineral rights belong to the Crown.
The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to t extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his right must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cen an acre per year and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affida that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre f SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the province of Quebec, north of t height of land, where important mineralized belts are known to exist.

Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, MONTREAL, for the dete mination, assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebe The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of t Province, on application addressed to

THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderat

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

WANTED

AGENCY FOR ORES AND MINERALS.

An Ore Merchant who has connections with all the blast-furnaces and electro-metallurgical firms of France desires to communicate directly with firms who produce or sell:—

Chrome Ore; India, Brazil, or Caucasus Manganese Ores; Graphite; Tungsten Ores; Molybdenite Antimony Ores; Iron Ores; and Asbestos.

It is desired to purchase Ores outright, or to take over Sales.

AGENCY FOR FRANCE:—

ANNOUNCEMENT

THE CANADIAN MINING JOURNAL'S

PORCUPINE SERIES

VOLUME I.

A SERIES OF UNIQUE ILLUSTRATED ARTICLES.

Accompanied by a Complete Geological Map and Claim Maps of the Various Townships

The Publishers of *The Canadian Mining Journal*, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. The latest available township maps and a large Geological Map will be included. The object of the publishers is to present in compact form a book that will guide the investor, the engineer, and the general reader.

The book will be on sale within a few days.

The price is $2.00 per volume. For orders of more than ten volumes a reduction of ten per cent will be made. The edition is limited.

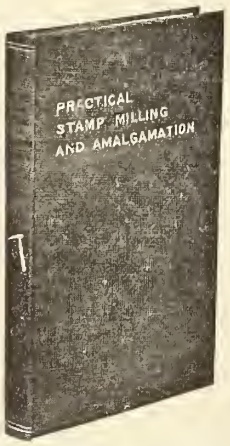
FOR THE MILLMAN

Practical Stamp Milling and Amalgamation

By H. W. MacFARREN

166 PAGES INDEXED

$2 POSTPAID



Written primarily for the millman himself, this book will prove of value to all those having to do with the milling of gold ores. Gives details needed in everyday work. The stamp mill, its location, and design; the mortar, die, shoes, tappet, and cam; adjustment of height, order of drop, feeder, and screens; water supply and power; principles of amalgamation and treatment of plates; retorting; loss of gold, mill tests, and mill management; all these are treated in an illuminating manner by one who has himself solved the problems.

ORE DRESSING

The School of Mining, Kingston, Ont., is prepared to make mill runs on **GOLD ORES** in lots of from 2 to 20 tons to determine average value, percentage of free milling gold and to recommend the best method of treatment,

Also **CONCENTRATION TESTS, ORE SAMPLING, and ASSAYING.**

Terms on application to

GEO. Y. CHOWN
Secretary of School of Mining
KINGSTON, ONT.

MINING & SCIENTIFIC PRESS

Controlled by T. A. Rickard — **Established 1860** — **Published weekly**
H. Foster Bain, Editor — **Thomas T. Read, Associate Edi**

In every issue valuable articles are published on mining, metallurgy and geology, the latest news from special correspondents at the principal mining centers, letters giving the ideas and experience of successful men, and other items of useful knowledge.

THE MINING MAGAZINE

Established September, 1909

T. A. RICKARD, Editor — **Published monthly at London, England**

A monthly magazine is the natural corollary of a technical weekly. It permits of more deliberate and more extended notice of matters concerning which the news element is less important.

The Mining Magazine includes a review of the world's progress in mining, metallurgy, and economic geology, written by men who have personal knowledge of the regions and conditions discussed.

Amatite ROOFING

For Mine Buildings

AMATITE is exactly suited to mining buildings because:

1—It can be laid by unskilled labor.

2—It has a real mineral surface *which requires no painting.*

3—Its cost is lower than that of other ready roofings of less weight.

4—It comes in rolls ready to be unrolled on the roof and nailed down.

5—The necessary nails and cement are supplied free, packed handily in the center of each roll.

The mineral surface of Amatite is somewhat of a novelty; and the fact that it obviates the old painting nuisance, is giving to this roofing the leadership of the ready roofing industry.

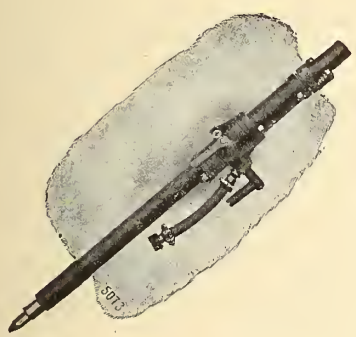
The surface consists of mineral particles embedded under great pressure into a tough plastic matrix of pitch.

A sample of Amatite will be sent free on request.

The
PATERSON MFG. Co., Limited
Montreal, Toronto, Winnipeg, Vancouver, St. John, N.B. Halifax, N.S.

TELESCOPE FEED

HAMMER DRILLS



The action of the Telescope Feed Hammer Drill, for up holes is far more economical of power than that of the piston type.

With the "BC-11" Telescope Feed Hammer Drill the steel is held loosely in the chuck and kept constantly against the clean surface of the rock under high pressure and is struck by the piston while this pressure is being exerted, giving a cumulative effect to the blow of the percussive force of the piston combined with the complete force of the air feed pressure.

Contrast this with the piston drill where so much energy is wasted in reciprocating the steel in the rough drilled hole partially clogged with dust and cuttings.

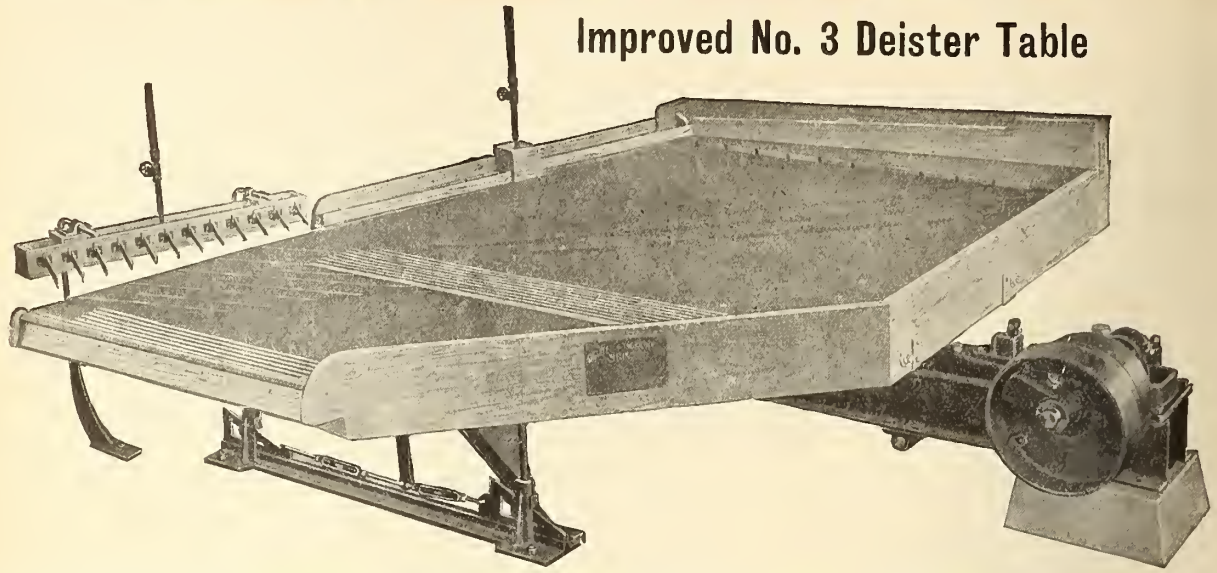
Improved No. 3 Deister Table



THE vanner has been a most efficient type of concentrating device for a decade. Competitive tests in such well-known mills as **Goldfield Cons. Mines Co., Goldfield, Nevada; Miami Copper Co., Miami, Arizona; Stratton's Independence, Ltd., Victor, Colorado; Old Dominion Copper Co., Globe, Arizona; Detroit Copper Co., Morenci, Arizona; and Ohio Copper Co., Lark, Utah;** have proven the Improved No. 3 Deister table superior in efficiency on feeds of 80 mesh and finer. A pleased customer remarks: "Your No. 3 Table does as good work for us as vanners at a tithe of the cost for repairs."

THE MESH KEEPS TRUE

It is easily possible for any coal mine superintendent to avoid the mis-grading due to faulty screens by always using

GREENING'S COAL SCREENING

We make this screening from a special hard steel wire drawn in our own mill. It is woven with a double crimp which not only assures perfectly square and uniform openings, but adds greatly to its strength as well as preventing displacement of the wires when in use.

We are Canada's pioneer manufacturers of mining screens, operating a particularly well equipped plant which enables us to quote the lowest prices, quality considered that can be obtained anywhere.

Why the C.P.R. North Toronto Route to Ottawa and Montreal is the Logical One

The train leaves as follows:

Leave North Parkdale - - -	9.15 p.m.	Leave West Toronto - - - -	9.30 p.m.
Arrive North Toronto - - -	9.40 p.m.	Leave North Toronto - - -	10.00 p.m.
Arrive Ottawa, 6.50 a.m.		Arrive Montreal, 7.00 a.m.	

Daily except Sunday.

¶ The residents of Toronto are adjacent to either North Parkdale, West Toronto or North Toronto stations, same being easily accessible and closer to residential districts.

¶ The North Toronto route is over an hour faster and overcomes a long hill climb for the train obviating any inconvenience and ensuring early arrival at Montreal and Ottawa.

¶ The roadbed has been improved till it is unexcelled in Canada. Practically half the line is double tracked.

¶ The equipment is "Canadian Pacific Standard," a synonym for the "best" and attentive porters, non-obsequious, ensure efficient service.

THE PORCUPINE DISASTER.

It was with sincere relief that the public learned, a few days after the Porcupine region had been swept by fire, that the loss of life was not nearly so large as was at first reported. In the excitement of the moment fears became rumours, and rumours became apparently authenticated facts. But before three days had elapsed the list of fatalities had dwindled from the hundreds to less than seventy-five.

Amongst the many Canadian cities and towns that immediately contributed to the relief of Porcupine, it were invidious to select any for special mention. No second appeal was necessary. Supplies and money flowed into the stricken town from every quarter. Even from London and New York money contributions were sent.

It is not invidious to express warm appreciation of the prompt action of the Temiscaming and Northern Ontario Railway Commission. Under the direction of Chairman Englehart, the orders were at once issued to exact no railway fares from the survivors of the fire. In short, the whole service was placed, as far as necessary, at the disposal of the sufferers.

On other pages of this issue are personal accounts of the tragedy. It is needless here to recount the details. The loss of life has been stated. The property loss cannot be more than very roughly estimated. In all probability it amounts to $2,000,000. This is serious enough. But the loss of time is quite as serious.

On the credit side of the account is the fact that in future much greater care will be taken, both in prevention of fires and in the construction of permanent buildings. It is already announced that the Dome Mining Company will erect an entirely fire-proof mill to replace the building that was destroyed. No doubt other companies will follow this example. Doubtless, also, the Ontario Government will reorganize its forest-protection system. It will also do its duty in the matter of enforcing restrictive regulations upon the storage of explosives. It is only by sheer good luck that many lives were not lost through the explosion of large quantities of dynamite. The control of this question must be taken up at once.

* * * * * * *

Porcupine is being rebuilt with all haste. Next year hardly a trace of the havoc wrought will remain. The way of the prospector has been made easier. Large areas, almost impossible for the prospector before the fire, have been cleared. Yet it will not do to forget the awful lesson of July. Human life is infinitely more important than property. Places of refuge must be supplied at every forest-surrounded mine. The most practicable refuge is the "cyclone-cellar." In course

of time the mines themselves will be extensive enough to afford a safe breathing place for the men. Meanwhile, no chances need be taken.

GEOLOGY AND MINING.

That there must be a closer line of demarcation drawn between the mining geologist, the common or garden variety of geologist, and the mining engineer becomes every day more apparent. Not long ago the *Canadian Mining Journal* expressed the belief that no person who does not possess the academic degree has a right to append the letters "M.E." to his name. He may, of course, have every right to use the words "mining engineer."

It appears to us that of all professional men, the trained geologist does not require a superfluous queue of letters behind his cognomen. No matter how many alphabetic feathers may be stuck in his tail, they impress only the unthinking.

But the assumption of the title and status of mining engineer by the geologist is not merely a question of good taste. Not seldom it brings grave discredit upon both professions.

Recently we were shown several reports upon mining properties, reports written by a geologist. All of these properties lie in the same region. Each of these reports contained a summary of the superficial geology of the region, a summary couched in hypertechnical terms. To the mining possibilities one or two paragraphs were devoted. No recommendation was made as to methods of prospecting or scale of equipment. The whole pith of the document was contained in one sentence that indicated the writer's belief that the veins were of deep-seated origin.

Now this kind of thing may be "geology," but it is not "mining geology," nor is it "mining." As the reports in question were accompanied neither by assay-maps, nor by any data as to cost of supplies, transportation, labour, etc., etc., they were absolutely useless as guides to the investor. Whatever vague references to mining they contained were of such a nature as to furnish ammunition for colouring a prospectus.

* * * * * * *

It is far from our intention to cast stones at the geologist *per se*. In initiative and in practical service he is second to none. But he gets into deep water when he confounds his proper functions with those of the mining engineer. The mining engineer often needs and requests the aid of the geologist, both in the prospecting stage and the later development of the mine. We have yet to hear of a mining engineer usurping the field of the geologist.

With the mining geologist, who is a relatively modern product, the case is different. His advice is required when geological problems arise affecting the future of a working mine, or in identifying the geological features of territory near established mines. Whilst his work necessarily indicates the scale upon which development may proceed, the actual plans for the future are determined by the engineer and modified by financial c-sideration.

In conclusion, it may be reiterated that the time s come for careful differentiation between the th branches of the profession. There will always be a c-tain amount of overlapping because the attainments a experience of every professional man vary. But in undignified confusion of to-day there is little of rea and less of dignity.

IMPOSING ON EUROPE.

On another page will be noticed a letter, sign "Germanicus." The writer of this letter is intimat acquainted with conditions of promotion and inve-ment both in Canada and Europe. His opinions entitled to respectful consideration.

The four maxims that our correspondent develops as follows:

"1. Every promising Canadian venture, which d
" not require millions, can be financed in Canada or
" the United States.

"2. Every larger enterprise demanding millio
" that can not be financed in the United States, becau
" the promoters have not the required connections the
" can be financed in London, provided it is sound.

"3. Every Canadian proposition that is being
" fered on the other side of the ocean by Americans
" to be considered as suspicious.

"4. Every Canadian venture offered on the C
" tinent, without a substantial reason for its being
" fered there, or without a most intimate and dir
" connection between Paris, Brussels, or Berlin, a
" the promoters, is more than suspicious."

Strong exception may possibly be taken to the sweeping generalizations. For instance, we know isolated cases where the promoter could not get a hea ing in Canada or the United States, despite the fa that his scheme was exceptionally sound. Often, al the vendor of a meritorious property feels that he w get better treatment on the other side of the Atlantic.

These exceptions, however, help to prove the rul To-day when all kinds of industrial schemes and eve variety of mining ventures are being taken over to Gre Britain and Europe, when the whole of Canada is bei raked over to secure something to sell, when, in fac Canada has become the chief hunting-ground of t adventurer, the warnings of our correspondent are har ly exaggerated. Where they may be unfair to the fe they embody cautions that should be carefully observ with all.

As a matter of fact, Berlin and Paris seem to be t dumping-ground of bad Canadian enterprises. T average business man of both these cities is unbelievabl ignorant of Canada. He hears only good of this cou try. And he becomes the ready dupe of the u scrupulous.

There are many reputable Canadians, of course, whose European connections permit them to lay proposals for investment before foreign investors. Our correspondent's strictures are not meant for them.

A NEW MILL.

In South Africa the Giesecke mill, a new modification of the tube-mill, is being tried out by the Mines Trials Committee.

The manufacturers of the mill claim that one Giesecke, with a capacity corresponding to 50 to 60 stamps, costs less than one-half the price of a stamp-mill of the same capacity.

The trial of the Giesecke is being conducted at the Geldenhins Estate. Here 50 stamps are hung up and the ore is being diverted to the Giesecke. The ore is in lumps as large as 7-inch cubes. The pulp at the discharge end of the mill is so fine that more than 80 per cent. passes a 200-mesh screen. Late reports place the capacity of the mill at 370 tons per day, the amount of water used being only 30 tons for each 100 tons of ore crushed.

The Giesecke mill is shorter than the standard size Rand tube mill. Of its entire length of 24 feet, one-quarter is of greater diameter than the rest of the cylinder. The larger end contains the larger steel balls, the portion of smaller diameter the smaller balls. The balls are in eight sizes, from 4-inch to 1¼-inch diameter. The two sections are divided by a screen or sizing plate. The steel balls weigh 23 tons in all, the liners 16½ tons, and the cylinder 15¾ tons. The charge is 9 tons, and the motive power required about 250 horse-power.

Amongst other claims advanced for the new mill, it is asserted that only a minimum of supervision is required and that lubrication is entirely automatic.

The Rand is making rapid strides in the metallurgy of gold. The existence of an official committee, whose duty it is to examine and test each notable invention or process, lends weight to any departures from fixed practice.

THE WESTERN STRIKE.

The strike of the coal miners in the Crow's Nest and Western Alberta districts is causing very serious loss. According to the estimate of Mr. A. C. Flumerfelt, the miners and employers are dropping about $20,000 per day. As the strike began on April 1st, the grand total that the strikers will be out on August 1st reaches the aggregate of $2,000,000.

There seems to be no sufficient reason why work should not have continued whilst the dispute was being settled in a rational manner. If the Industrial Disputes Act means anything, if it is to be anything but an added source of expense and strife, it surely should be effective in promoting the continuance of work and the peaceful arbitration of differences.

What is really required is the abolition of the haphazard choice of inexperienced and inapt chairmen. This lesson was well illustrated by the satisfactory settlement of the Dominion Coal strike. In this case, Dr. Adam Shortt, an official of eminently sane and judicial mind, brought operators and employees together with a minimum of noise and friction. It is a grand pity that some similarly diplomatic person could not have been made chairman for the committee that reported upon the Western strike. Incidentally, all the futile exchange of amenities in the public press would then have been avoided.

It is clearly evident that Dr. Gordon, as chairman, was out of his depth. The wording of his report was indiscreet and painfully florid. Neither in experience nor in temperament is a man of his type suited to the task of dealing with problems in real life.

EXPORTS AND IMPORTS OF CANADIAN MINERALS.

During 43 years, covering the period 1868-1910, inclusive, according to the statisties collected in the Canada Year Book, a Government publication, Canada has exported mineral produce valued at $530,920,916. The great bulk of this has gone to the United States, that country taking no less than $475,292,324, or, roughly, 90 per cent. of the total. Great Britain is a bad second, with only $29,838,991 to her credit. The remainder, $25,789,601, was distributed in small amounts to many other countries. Thus, whilst we have shipped nine-tenths of our mineral exports to the United States, we have sent only 5.5 per cent. to Great Britain.

In the export returns for the year 1910, the relative position of Great Britain shows a slight improvement over the general average. Of our mineral exports she took about 9.5 per cent., whilst the United States took approximately 83.5 per cent.

Whatever errors there may be in these figures, and it is undeniable that our official statistics are far from correct, they are relatively accurate. In the aggregate, they probably do not wander from the truth by more than 10 or 15 per cent. A closer analysis of the distribution of exports is unnecessary. The comparison between our two chief customers is sufficient. And the facts must be faced, no matter what our feelings as private citizens may be.

There is room for speculation as to the probable effects of complete free trade in mineral commodities with Great Britain or the United States, or with both. There is no doubt about our present position.

A GENEROUS COMPANY.

More than passing notice is due the T. Eaton Company for the exemplary despatch with which a carload of provisions and clothing was sent to Porcupine. News of the fire reached Toronto on Tuesday evening, July 11th. On Wednesday a carload of 20,000 pounds

of provisions, clothing, blankets, bedding, and sundries, including large quantities of first-aid materials, was got together. On Thursday morning the whole lot was sent off by express, reaching Porcupine on Saturday morning. Nothing could have been more timely.

The incident shows what perfect organization, combined with human kindness, can accomplish.

EDITORIAL NOTES.

There are now 67 gold-producing companies operating in the Transvaal. Altogether 9,941 stamps are in commission.

What action the Government of Nova Scotia will take in regard to the flooding of the Port Hood submarine areas is not yet announced.

Keen interest is being manifested in gold mining in Lake of the Woods and Sturgeon Lake. A number of Toronto mining engineers and operators are developing prospects and re-opening abandoned mines.

Dr. A. S. Mackenzie has been elected president of Dalhousie University. Dr. Mackenzie's record in several professional chairs is thoroughly good. He is a Nova Scotian. He will probably occupy the chair of physics.

A strictly followed tradition has hitherto kept from the coinage of Mussulman countries the representation of living creatures. Now, however, the Bank of Morocco has placed with the Paris mint an order to strike silver coinage bearing the effigy of Mulai Hafid.

The British Radium Corporation, Ltd., a subsidiary of St. Ives Consolidated Mines, has already sold $50,000 worth of uranium oxide and radium extracted from pitchblende mined at the Trenwith mine, Cornwall, England.

Canadian coal is being tested by the United States navy. The flagship of the second division of the Pacific fleet, the "West Virginia," has taken on 900 tons each of Comox, Nanaimo, and South Wellington coal. The coal will be given a thorough test. Eleven days of steaming will be required to complete the trials.

The average annual profits of the Mond Nickel Company for the past five years have been £122,239. In 1911 the profits were £148,214. The authorized capital is £850,000. The preferred stock, £400,000 issued, pays 7 per cent. The ordinary shares have paid from 12½ to 16¼ per cent., and substantial dividends have been distributed on the £50,000 of deferred shares.

The Hillcrest Collieries, Limited, operating the Hillcrest coal mine, situated near Frank, Alberta, on July 15 paid its second dividend of 1¾ per cent. on its preferred stock. The total of dividend was $12,350. A similar amount having previously been paid, the total of dividends paid to date is $24,700.

Personal and General

Mr. J. B. Tyrrell has left for a short visit to Lon. He will return to Toronto in September. His Lo address is 224 Salisbury House, E.C.

Mr. R. B. Lamb, Toronto, is leaving on an exte trip to Cobalt, Porcupine and Swastika, to inspect properties with which he is connected.

Lieut.-Col. R. G. Edwards-Leckie and Captain H. Kirkpatriek are inspecting several Portland C mining properties, including the Lordigordy, F Portland, and American Creek.

Mr. Chester Wells Purington has taken office number 62 London Wall, London, E.C. Mr. Pu ton's specialty is the examination of mining prope in the Russian Empire.

Mr. C. F. Dike, jr., general manager the C Charter, Porcupine, visited Montreal and Toront business shortly after the fire. He has returned to cupine, accompanied by Mrs. Dike.

Mr. J. M. Turnbull, one of the mining engineer the staff of the Consolidated Mining and Smelting pany of Canada, Ltd., has lately been engage examining mining properties in the Skeena district,

Mr. M. K. Rodgers, of Seattle, Washington, who, working under a roving commission to find mines the late Mr. Marcus Daly, chose the Nickel Plate gr in the Similkameen district, and the Hidden C group, near Observatory inlet, as likely to meet th quirements of his principal, is still giving attentic British Columbia.

Mr. W. C. Thomas, formerly manager for Dominion Copper Company, at Boundary Falls, recently visited Portland Canal district, with a vie advising the company owning the Red Cliff copper concerning the selection of a site for a smeltery sh it be found desirable to establish local copper redu works for Red Cliff ore.

Mr. C. D. Emmons, of Eugene, Oregon, who is a in an advisory capacity to the B. C. Oilfields, Ltd Vancouver, B.C., recently again went north the scene of the company's operations, on west coast of Graham island, of the Queen Char group. A standard drilling plant is in use, and hoped oil will be found in the bores being put dow

Mr. W. H. Trewartha-James, general manager o Tyee Copper Co., Ltd., has returned to his head arters at Victoria, B.C., from a business visit to mi camps in south-eastern Alaska, southern Yukon, northern British Columbia. The Tyee Company's ing and smelting business covers practically the Pacific coast, from the west coast of Mexico to Al

Mr. W. Satchell Clarke, of Vancouver, B.C., charge of the B. C. Drilling and Dredging pany's drilling operations on Tulameen River, the gravel is being systematically tested in pros ing for placer gold and platinum. At present wo being done along the river above the town of Tulam long known as Otter flat. Several streams tributa the Tulameen yield both gold and platinum.

Mr. William Fleet Robertson, provincial mine gist for British Columbia, is engaged this summe examining, and obtaining information relative to mineral-bearing district around Hazelton, in the Sk River country, in which the occurrence of both me and non-metallic minerals is known, and prospe have been at work during parts of several recent y

Geological Survey of Canada is also continuing ork in this district.

cials of the Granby Consolidated M., S. and P. td., were at Goose bay, Observatory inlet, last , determining the nature of further development to be done on the mining property the com- has purchased from the Hidden Creek Copper g Co.; also deciding what surface improvements be made to ensure greater economy in the expen- of the comparatively large sum appropriated for the mine, with the object of making its immense of ore available for extraction at low cost.

D. A. McMillen, chief consulting engineer of the Exploration Company, 64 Wall Street, New City, is at present spending a few weeks in Cen- nd Southern Mexico, where he is examining pro- s for the interest of his company. About August e will go to the State of Sonora, where he will ue his investigations and examinations of cer- silver properties. Mr. Horace H. Howard, also lting engineer for the same company, is at pres- oing special consulting work in the Porcupine dis- He was in Porcupine at the time of the disas- forest fire and narrowly escaped death from ng.

Correspondence

CANADIAN PROJECTS AND THE EUROPEAN INVESTOR.

Editor Canadian Mining Journal, City.

,—The recent attempt to sell Porcupine mining on the Continent, stock in a prospect where no gold ings exist, on which no report of a mining engineer blished; and the further attempt to finance a coal- osition in the Crow's Nest area, where the owners only the hope of discovering the seams which their bours are supposed to have, induce me to issue a energetic warning on the Continent, in order to uard future *bona fide* Canadian enterprises. This ing I have couched in the following maxims:

1 Every promising Canadian venture, which does require millions, can be financed in Canada or in the ed States.

2 Every larger enterprise demanding millions that not be financed in the United States, because the oters have not the required connections there, can nanced in London, provided it is sound.

3 Every *Canadian* proposition that is being offered *Americans* on the other side of the Ocean is to be idered as suspicious.

4 Every Canadian venture offered on the Continent, out a substantial reason for its being offered there, ithout a most intimate and direct connection be- n Paris, Brussels, or Berlin, and the promoters, is than suspicious.

ll of us have every reason to stop such proceedings.

Yours truly,

GERMANICUS.

he Spokane Asbestos Fire Brick Company will tly erect in Spokane, Washington, U.S.A., works will be equipped for the manufacture of various conducting materials. The asbestos property owned the company is situated 14 miles south-east of miah, Idaho.

ZINC ORE REDUCTION EXPERIMENTS.

In the course of an address on the Reciprocity issue he made at a public meeting held at Nelson, British Columbia, on July 10, Hon. Wm. Templeman, Dominion Minister of Mines, is reported by the Daily News to have said: "Some friends in this city asked me to-day concerning the matter of the experiments in connection with the reduction of zinc ores. Well, at present I have not very much that is specially new to say on this subject. I have some knowledge of the zinc question and also of lead. Some years ago we gave a bounty on the production of lead, and this has still a year or two to run. But what to do with our zinc ores has for years been a question with the miners of this country.

"At the request of the people of this city we took up the question of the electrical smelting of zinc ore. I had $50,000 set aside for carrying on experiments, and these experiments are still going on. I secured the services of W. R. Ingalls, of New York, who is said to be the greatest expert in zinc on this continent. We also submitted certain problems to be solved in the laboratory of McGill University by Professor Stansfield, a young electrical engineer, who has made great progress in the study of such problems, and the report of Dr. Haanel is that these experiments are meeting with considerable success, and he hopes at an early date to be able to make a report that will satisfy the mining interests, and that something definite will be achieved. However, I am frank to say that trying to discover a new process of zinc smelting is something that no one can say is certain to succeed.

"It has been suggested—why did we not negotiate an agreement with the United States for free admission of our zinc ore? Now that is something I am fully in favour of, until such time as we shall be able to smelt it successfully in Canada. Let me take you into my confidence and tell you this—that Hon. Mr. Fielding, at my request, pressed that very point on the American representatives, but was unable to get them to agree to admit zinc ores and lead, the interests on the other side being too strong. So we are still trying to discover a method of smelting our own zinc ores, and I hope we shall succeed. We shall keep on until the whole $50,000 shall have been spent, anyway; though we have not yet spent very much of the amount."

The opinion that bornite ore does not occur at depth is by no means uncommon, for it is frequently expressed in some copper mining districts. For instance, several years ago the manager of the Marble Bay mine, situated on Texada Island, British Columbia, was told by visiting mining men of experience and good professional standing that the bornite ore then being mined there would not "go down." However, it was afterwards proved that it did go down, for during the last year it has been mined on the 1,100-ft. level, and its continuation down to the 1,200-ft. level was expected with confidence. On July 1 The Mining Journal, London, England, included the following in its correspondence from Australia: "It is stated that at the North Mount Lyell mine, Tasmania, very rich ore continues to be won at the 1,100-ft. level. A specimen block of solid ore that has been brought to the surface is of marvellous richness. It weighs half a ton, and consists of bornite largely associated with copper glance, the copper contents being estimated at 60 per cent., while the approximate value of the specimen is £15. There are said to be hundreds, and probably thousands, of tons more of similarly rich ore existing in the stope whence came the specimen in question."

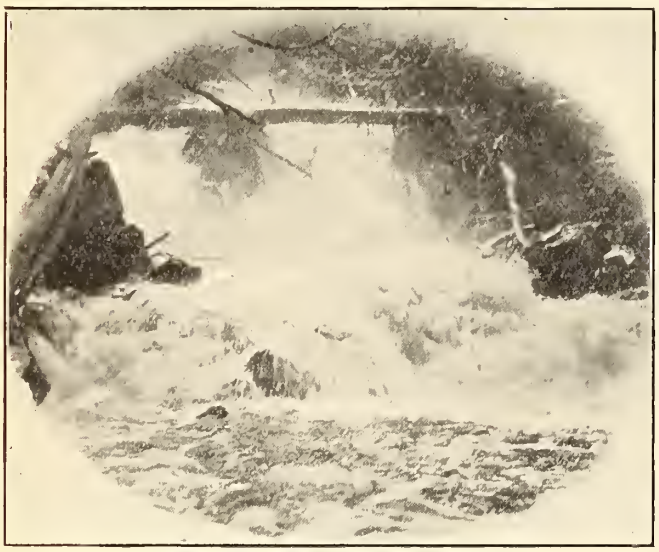
GOWGANDA & ELK LAKE RAILWAY

Special Report of A. B. Willmott for Operators.

Mr. M. L. Foley, President,
The Gowganda & Elk Lake Mining Association,
Toronto, Ontario.

DEAR SIR,—

From March 12th to March 24, in company with Messrs. Cole and Mickle, representing respectively the Temiskaming & Northern Ontario Railway and the Provincial Government, I made an inspection of the working mines and some of the prospects in Elk Lake and Gowganda. The object in view was the determination of the probable freight which a railroad would secure if built through that section of country. While the snow roads afforded a quick and easy means of transport, the snow itself prevented the examination of many promising properties. In a few cases the prospectors had cleared off the snow from promising shows at considerable labour and expense. More frequently nothing was to be seen at many of the most promising prospects. We visited 23 properties in all. The names of 36 others, which are said to have promising veins, were handed to us by the local committee. Scores of other claims have been staked in the country, many of which will doubtless prove of equal value when developed.



Hanging Stone Falls, Gowganda

Stoping out Concentrating Ore at Millerett Mine

The adverse conditions under which development work is progressing in this district are so well known to you that it is superfluous for me to mention them. Nor need I present any argument to you as to the necessity for a railroad if the region under discussion is not to go back into its original wildness. The argument should rather be directed to the people of the Province of Ontario, who are quite as much interested as you in the subjection and development of this wilderness.

Why the People of Ontario are Concerned.

From a sentimental reason Ontario as a whole is interested in the development of Northern Ontario which constitutes two-thirds of the Province. It is important to us as Canadians that the uninhabited territory north of the Great Lakes should be settled. Wherever resources occur, be they timber or mineral or agricultural lands, the people of the Province are interested in seeing these utilized and prosperous communities founded.

Apart from the sentimental reason the people of Ontario are concerned because the development of these resources adds to the revenue of the Province. The revenues from northern Ontario have in the past obviated the necessity of direct taxation. Elk Lake and Gowganda have contributed very largely, and these revenues are to continue better facilities for development of the country must be provided.

The whole of this territory is owned primarily by the people of Ontario. When a mining claim is leased to an individual they very properly require that assessment work shall be done, and that the property shall not lie idle. The principle lying back of the assessment work is that undeveloped properties are useless to the Province as a whole. The largest owner of undeveloped properties is the public itself. If it is right to require the private owners of mineral lands to develop these lands it is also right to require the public to develop their part. One cannot ask that the public shall go into the exploration of mining claims but one can demand, and quite fairly, that the public shall bear their part of the cost of development by providing proper transportation facilities.

The people in older Ontario fail to realize the great distances between railroads in the north country. For instance, from Charlton, the terminus of the railroad to Gowganda, a distance of about 45 miles, is considerably further than from Toronto to Hamilton, and owing to the character of the roads, is quite as serious in the matter of freight as to have to haul by team from Toronto to Brantford.

The teaming of 100 h.p. boilers and other machinery from Toronto to Brantford, would be a most serious drawback to the development of the latter city if that were the only means of transport, and yet that is the condition in Gowganda. It is thus not surprising that the people in the north want railroads built by the province or that public assistance be granted private companies to encourage them to build. The increase

in alue to the public of the unoccupied lands warran such action.

Why a Railway is Necessary.

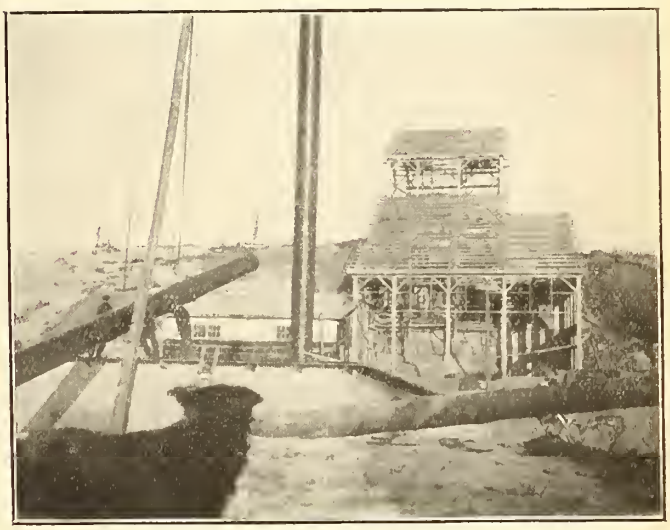
Compared with Cobalt, the Elk Lake-Gowganda district is a low grade camp, though in comparison with many silver districts of the world its ore would rank as high grade. Cobalt has the advantage not only of enormously rich ore, but of low freight rates, as compared with most mining camps. For this reason profits of mining there have been unusually great, and the necessity for close scrutiny of working costs has not arisen. In Elk Lake and Gowganda, on the contrary, the closest attention to detail is required and every expense must be carefully scrutinized just as in all industrial business. There are properties which could undoubtedly be made to pay, to the profit of their owners and to the advantage of the Province as well, if proper transportation facilities are afforded. The cost of supplies at present is tremendously high. For instance, hay at Charlton is worth $15 a ton, and at the Boyd-Gordon mine $38 a ton. One mine manager shoveled me ten tons of blacksmith coal which cost him in his shed $40 a ton. Properties on the west side of Gowganda Lake are paying $1.35 to $1.50 freight per hundredweight from the railway to their properties. At Hanging Stone the winter freight is $2 per hundredweight, and in summer $6 per hundredweight. When it is recalled that an average freight rate on Canadian railways is about 2 cents per ton-mile, and that the winter freight to the west side of Gowganda is 80 cents per ton-mile, or thirty times as much, the serious handicap from the lack of transportation is evident. Many items of consumption cannot be foreseen and have to be brought in in the summer time at a cost of $1.60 per ton-mile, or eighty times ordinary freight rates. This applies to the west side of Gowganda Lake. To Hanging-Stone Lake the charges are considerably higher.

Raising No. 1 Shaft house, and camp in background, Millerett Mine.

The cost of labour is also greatly increased by the remoteness from transportation. In the first place, 25 cents a day on the average over Cobalt prices is paid to all employees. Moreover, the cost of board averages fully 25 cents a day more per head. At a prospect employing 50 men, this amounts to an increased cost for labour of $25 per day, or $7,500 per annum. To this is to be added the increased cost of all mining supplies, as dynamite, steel, tools, and fuel.

Another adverse condition is the loss of time in securing men and supplies. The mail service, particularly spring and fall, is interrupted, and annoying delays occur in securing repair parts and supplies not foreseen. The loss of time in securing men to take the place of some who may have suddenly ceased work is also vexatious and costly.

Still another serious handicap to the development of this region is the difficulty of interesting capital. Promoters and investors were readily taken to Cobalt on comfortable trains, and so easily and quickly were shown the possibilities of that camp. Such men can only be taken to Gowganda with any comfort in the winter time, when the very things which it is desirous to show them are hidden by a thick mantle of snow. In the summer time slow and laborious canoe trips, with exposure to uncertain weather and insect pests, prevent many a possible investor from investigating the camp. Undoubtedly had Gowganda had the same advantage as Cobalt, much more capital would have been invested, to the advantage of the camp and the Province generally.



Raising a Stack on New Boiler House and Mill Framework behind

The Proposed Railroad.

On an accompanying sketch map the mining divisions of Gowganda and Montreal River are shown and the railroad facilities of the southern part of Nipissing district. It will be observed that the Temiskaming & Northern Ontario Railway runs a litle west of north from North Bay, and that the Canadian Northern Railway runs a little west of north from Sudbury. The first connects with the Grand Trunk Pacific at Cochrane, outside the limits of this map, and the second is to be extended north and west to Port Arthur. These two roads are approximately sixty to seventy miles apart. The proposed road from Charlton, on the Temiskaming & Northern Ontario Railway, to Gowganda Junction, on the Canadian Northern Railway, runs at right angles to the two roads, and would be about 95 miles in length. From Charlton via Elk Lake to Gowganda in a straight line is 40 miles. The country from Charlton to Elk Lake is fairly easy for railroad construction, but from Elk Lake to Gowganda numerous ridges have to be crossed, neeessitating a considerable increase in length of road. Surveys have been made by the Temiskaming & Northern Ontario Railway, and I understand the proposed road would have a length of about 50 miles.

From Gowganda city to Gowganda Junction, on the Canadian Northern, is 38 miles in a straight line, and

ad would probably be built with a length not exing 45 miles. This road would largely follow the r valleys and would be easier constructed than that n Elk Lake to Gowganda city.

he eharaeter of railroad required may be a matter pinion. Personally, I believe that for the present heaply eonstrueted standard gauge road would e every purpose. With rails of 60-pound weight roadbed in proportion, eost of eonstruetion should bout $20,000 per mile. As traffie warranted it, road eould later be improved. If a road were pleted through from the Temiskaming & Northern ario to the Canadian Northern, the capital cost ld thus be $1,900,000. or say $2,000,000.

Richly Mineralized Area.

efore considering the amount of traffic for the proed road, it would be well to consider the character ountry through whieh it will run. On the accompying map it will be noted that a wide band of rocks Keewatin and Huronian age are shown as running theast from the Georgian Bay, past Sudbury and alt, to the Quebee boundary. These roeks are haded on the map. Adjoining them to the north l south, and cross-lined on the map, are granite and iss of Laurentian age. The latter are almost devoid economie minerals. The former are the great minl bearers of Ontario. These roeks earry the iron s of Miehipieoten and Moose Mountain, the copper of the north shore of the Georgian Bay, the nickelper ore of the Sudbury region, and the eobalt-silver s of Cobalt and adjoining regions. The total value the nickel and eopper production of Sudbury, as npiled from returns published by the Geological rvey of Canada, amounts to no less a figure than 8,773,700. The value of the total output of the Colt camp in silver amounts to $48,327,280, in which account is taken of the value of eobalt niekel and senic. After long investigation throughout the whole ovince, I am thoroughly convineed that the Huronin belt under eonsideration is the richest portion of e province in minerals.

On the map a few of the oeeurrences of silver roughout the Gowganda-Elk Lake district are own, from which a very wide distribution of that tal is apparent. Scores of claims have been staked this distriet with native silver showings, and many these have been developed into encouraging prosjcts Two, at least, are now in the position of produeg mines, with every probability of being dividend yers. It is to be noted that in these properties the ver ore oeeurs in diabase, and that, eontrary to genl impression, dividend-payers have been found in is formation. At least six properties are loeated in e diabase of Cobalt and Gowganda whieh are in the vidend class. Numerous occurrences of native silver rrying several thousand ounees to the ton, were own us. Undoubtedly some of these will make proeing mines. Only a small fraction of the eountry s been trenehed, and if the present population is inced to remain in the distriet through giving them ilroad facilities, rich discoveries of silver will be ade for years to come.

On the Wapoose River and near Shining Tree Lake, n formation oeeurs similar in eharaeter to the Michipoten iron range and the Vermilion iron range of innesota. I am told that one deposit on the Wapoose ver is as promising in its surfaee appearance as was oose Mountain. Unfortunately, none of our party s seen this property.

Fuel.

The prospects and mines are at present dependent on an inferior quality of wood as a souree of power. At least 2¼ cords, even after drying for six months, are required to yield the equivalent of one ton of good coal. The wood is soon eut off a 40-aere claim, and then purehase must be made from adjoining claims. At the Millerett the cost of wood was stated to be as follows:

Stumpage to the Booth Company	12½c a cord
Stumpage to the Provineial Government.	12½c a cord
Stumpage to claim owners	25c a cord
Total stumpage	$0.50
Cutting	1.25
Hauling	1 50
At the boiler in winter time	3.25
At the boiler in summer time	3.35
Average eost per cord	3.30
2¼ cords wood	7.42

Three-quarter lump best Pittsburg coal would be supplied at the Millerett for $4.25 by way of the Great Lakes, Key Harbour and the Canadian Northern or for $6.25 by all rail route via the Temiskaming & Northern Ontario Railway. The saving by the first route

Power plant, Mill, and No 1 Shaft. All dumps to left of shaft are Concentrating Ore.

over wood fuel amounts to $3.17 per ton of coal or on the estimated consumption of the Millerett yearly namely 1,900 tons, $6,023. The eost of coal by the two different routes is estimated as follows:

Price of coal, f.o.b. Suspension Bridge	$2.50
Duty	.53
Freight by G.T.R. and T. & N. O. to Charlton 455 miles, being one-half cent on the former and three-quarters cent on the latter per ton mile	2.85
Freight, Charlton to Millerett, 50 miles at three-quarters cent per ton-mile	.37
Total	$6.25
Coal, f.o.b. boat Cleveland	$2.25
Duty	.53
Boat to Key Harbour and unloading	.57
C. N. R. to Gowganda Jet. and Government extension to Millerett, 155 miles, being one-half eent on the former and three-quarters eent on the latter per ton-mile	.90
Total	$4.25

There are already installed in Gowganda and Elk Lake boilers rated at 3,300 h.p. These would require annually about 23,000 tons of coal were they supplied altogether by coal. Many of the smaller ones not di-

rectly on the railroad would probably continue to use wood. As there are few water powers in the district it is probable that for many years, mines in this district will be supplied largely by coal.

The coal requirements of the Temiskaming & Northern Ontario Railway at Englehart, which amounted last year to 22,645 tons, can also be much more cheaply supplied by way of the proposed railroad. The cost of coal delivered at Englehart by the present route and the proposed route work out as follows: Coal on board cars at Suspension Bridge costs 25 cents more per ton than the same coal on board boat at Cleveland. The freight rate on the Grand Trunk from Suspension Bridge to North Bay is $1.75, or approximately one-half cent a ton-mile. The same freight rate is allowed the Canadian Northern for a haul from Key Harbour to Gowganda Junction. The present rate on the Temiskaming & Northern Ontario from North Bay to Charlton is three-quarter cent per ton-mile, and for purposes of comparison this rate is assumed both on the present road and on the proposed road. Coal on board cars Suspension Bridge, duty paid $3.03, freight to North Bay $1.75, North Bay to Englehart $1., total $5.78. Coal, f.o.b. boat, Cleveland, duty paid $2.78, boat freight to Key Harbour and unloading 57 cents, Canadian Northern to Gowganda Junction 55 cents. Gowganda Junction to Englehart 78 cents, total $4.68. This shows a saving of $1.10 on every ton of coal required at Englehart. On a consumption of 22,645 tons, the saving per annum to the railway company on its own coal through importing by way of the new railroad, amounts to $24,909.50.

The coal requirements at Cochrane, a divisional point on the Grand Trunk Pacific, are now brought in all rail, by way of the Grand Trunk and the Temiskaming & Northern Ontario. A similar saving of $1.10 a ton can be made on all this coal by importing by way of Key Harbour. The probable consumption at Cochrane is unknown to me, but may be put at twice the consumption of Englehart. This should give the proposed road an additional freight tonnage of 50,000 tons, yielding in freight $38,500, at three-quarters cent per ton-mile. It is further to be noted that if the freight rate to Cochrane on coal can be reduced $1.10 a ton over the present rate a longer section of the Grand Trunk Pacific will be coaled from Cochrane, making that much more freight for the Temiskaming & Northern Ontario.

Probable Traffic.

The probable traffic for such a road is very hard to estimate accurately, and the figures given below must be accepted cautiously, but they are believed to be quite within the bounds of probabilities. The best developed mine in the region is the Millerett, and the manager of that property made the following estimate of the traffic he would furnish during the next two years:

Ore and concentrates, 400 to 500 tons per annum.
Coal, 1,800 to 2,000 tons per annum.
Supplies, 300 to 500 tons per annum.
An average of, say, 2,800 tons.

In addition he figured 400 to 500 passenger fares per annum between the Millerett and Charlton. He has paid out during the last two years for freight between the railroad and the mine $46,000. His freight in winter, when it is the cheapest, costs $20 a ton, or at the rate of 45 cents per ton-mile. He would consider that if his freights were divided by ten, that is, if brought down to $2 per ton, that it would be of the very greatest advantage. All operators recogn that the freight on the branch road should be hig than in older Ontario, and would raise no objecti to this.

After seeing a large number of the properties in district, I think one may fairly assume that with r sonable transportation facilities such as here ad cated, at least ten operating mines similar to the M lerett may be looked for within a few years. Tak the average tonnage of these properties at 2,800 t per annum and the average freight rate at $1.50 ton as the average haul would be less than to the M lerett, the total freight would amount to $42,000 annum. We may fairly assume that at least fo prospects would begin operation and that these wo each require one-eighth of the supplies required by better developed properties, making a total freight $21,000. To these probable freight receipts from mines must be added the freight requirements of towns of Gowganda and Elk Lake. There will a be passenger fares, which should amount to $10,00 year. Telegraph and express receipts should something additional. There will be further the frei on a certain amount of pulp. On coal for the Gra Trunk Pacific the additional receipts should be $ 000. The total receipts from all these sources sho be considerably over $100,000 annually. Should i ore in commercial quantity be found, the receipts n easily be doubled. Assuming that working expen will be sixty-five per cent., there would appear to a profit of $35,000 for interest on capital account. this is to be added the saving on coal for the m line of the Temiskaming & Northern Ontario, amou ing to $25,000.

Financial Considerations.

The revenue to the Province of Ontario from mining divisions of Montreal River and Gowganda past four years has been as follows:

	Montreal River	Gowganda	To
1907.	9,441.15		
1908.	25,177.25		
1909.	49,395.67	$42,583.65	
1910.	16,403.03	15,512.45	
	$100,417.10	$58,095.10	
Average	25,104.27	29,047.55	$54,151 2

This revenue included miners' licenses, fees and ceipts from sale of lands, but does not include recei from the sale of town lots in Smythe and Gowgan It does not include the receipts from part of the S bury mining district around Welcome Lake, wh would be served by the proposed railroad, but on contrary does include some receipts from the south part of the Montreal River division, which would be served by the railroad. Some receipts are not cluded which were collected at Toronto, and this particularly true of the first and second years.

I am convinced that if proper transportation fac ties are not given these two mining divisions, that receipts to the Province will rapidly dwindle alm to the vanishing point. If, on the contrary, a railw is built, the people who are in there will take fr heart and will interest more capital in their propert new properties will be discovered and the provinc revenue will continue. It will be noted that the av age receipts total a little over $54,000, and proba nearly $50,000 is net. No income is here included fr working mines. This might easily amount to $25, or more. It is very safe to assume that a railway

$50,000 per annum to the provincial revenues over it will be obtained without it.

Assuming that the railroad will cost $2,000,000 and interest is payable at the rate of four per cent., yearly charge will amount to $80,000. Against this have net profits on the operation of the railroad as shown above, amounting to $35,000, additional net profit from miners' licenses, etc., of $50,000, and saving in coal to the railway of $25,000, a total of $110,000.

Conclusions.

I am aware that the figures given as the probable profits may be challenged and that such estimates are uncertain. Even if no profit could be made on the railroad, I would still urge on the people of the Province the desirability of the construction of the railroad. A good start has been made on the development and permanent settlement of this section of the Province. Should the people now there become discouraged and leave, it will put back the development of that section half a century. An estimate prepared by ourselves shows that the principal companies have already expended in that country three and a half million dollars, and the expenditure by individuals must largely increase this amount. You have taken your share in the risk of development, the people of the Province should bear their share in the risk, by constructing the transportation facilities which are absolutely necessary Nor do I believe that this expenditure on the part of the Province would be any great risk. Every railroad which has traversed this mineral belt has developed remunerative traffic. The Canadian Pacific at Sudbury has been the means of developing the largest nickel field in the world. The Temiskaming & Northern Ontario Railway at Cobalt, crossing the same belt, has developed the richest silver camp in the world. The Canadian Northern, crossing the same belt, has opened up some of the richest nickel and iron mines of the Dominion. A road from Gowganda Junction to Charlton will in all probability be the means of opening up similar mineral riches.

Had the promoters of the Canadian Pacific hesitated to build from Ottawa to Port Arthur until payable traffic could be shown, there would have been no Sudbury and its nickel mines. Had the promoters of the Temiskaming & Northern Ontario waited until payable traffic could have been shown, there would have been no Cobalt. Railroads into new territories are in a measure speculative, but so many of them have made good, and particularly in this mineral belt, that I have no hesitation in urging on the people of Ontario that this road should be constructed. Several railroads now under construction in the Province by private capital do not promise nearly as well. If private companies are willing to take the risk involved in these railroad undertakings for the possible profits that may accrue, surely the great Province of Ontario can afford to build a railroad from the Temiskaming & Northern Ontario to the Canadian Northern at Gowganda Junction through the richest mineral area of the Province.

All of which is respectfully submitted.

404 Lumsden Building, A. B. WILLMOTT.
Toronto, April 3, 1911.

MINERAL PRODUCTION OF BRITISH COLUMBIA IN 1910

(By E. Jacobs, Victoria, B.C.)

The Annual Report of the Minister of Mines of British Columbia for the calendar year 1910 was issued early in July. The net results may be gathered from the first two sentences of the review of the year by the Provincial Mineralogist, Mr. William Fleet Robertson, under the head "Progress of Mining," as follows: "The value of the mineral products of the Province for the year 1910 amounts to $26,377,066, which is considerably greater than that of any previous year. The tonnage of ore mined in the lode mines during the year was 2,216,428 tons, an increase over that of the preceding year of 158,715 tons, or 7.7 per cent." It might have also been stated that this is the largest tonnage for any year since the commencement of lode mining in the Province.) A third sentence, appearing later in the review, is necessary to complete this brief summary of the year's results, namely, that "the production of coal made by the British Columbia collieries during 1910, amounting to 3,139,235 long tons, was the greatest in the history of coal mining in the Province."

Several of the statistical tables follow, these exhibiting, respectively, (1) the value of the mineral production of the Province for all years to 1910, inclusive; (2) the quantities and value of mineral products for three years, 1908-1910; and (3) the value of the production of the several districts and divisions into which the Province is officially divided.

In calculating the value of the products, the average prices for the year in the New York metal market, as shown by The Engineering and Mining Journal, have been used as a basis. For silver, 95 per cent.; for lead, 90 per cent.; and for zinc, 85 per cent. of such market prices have been taken. Treatment and other charges have not been deducted, except an allowance of 5 lbs. of copper to the ton of ore smelted for loss in the slags.

The quantity of ore shipped to smelteries or treated in concentrating or stamp mills has been obtained from certified returns received by the Provincial Department of Mines, as provided for by law. As regards "Other Materials" shown in the second table here reprinted, which item includes building-stone, lime, bricks, tiles, portland cement, etc., although it is not so stated in the report, it is known that the total value of these products appearing in the table is well within the actual value of the production of the year, additional details received after the table was made up having proved the estimate to be under, rather than over, the amount included.

Value of Total Production for all Years to 1910, Inclusive.

Gold, placer	$71,213,103
Gold, lode	60,811,067
Total gold	$132,024,170
Silver	31,095,602
Lead	24,645,605
Copper	60,743,405
Other metals (zinc, iron, etc.)	1,083,172
Total metalliferous	$249,591,954

Coal and coke	$114,012,596
Building materials, etc.	10,593,100
Total non-metalliferous	124,605,696
Aggregate value of production	$374,197,650

Summarizing the foregoing, the various classes of mineral production are as under:—

	Total value.
From placer mines	$ 71,213,103
From lode mines	178,378,851
From coal mines	114,012,596
From quarries, etc.	10,593,100
Aggregate value	$374,197,650

It is noteworthy that the aggregate value at the end of 1910 ($374,197,650) shows an increase in ten years of $222,042,442, or about 146 per cent., over that at the close of 1900 ($152,155,208). Comparing 1 ($248,663,176) with 1900, the increase in five years $96,507,968, or about 63.5 per cent., while the five-y period, 1906-1910, gave an increase of $125,534,474. nearly 51 per cent., the aggregates at the end of 1 and 1910, respectively, having been as shown above.

The quantities of the several minerals produced in the Province in all years is shown in the statistical tables to have been as under (placer gold, of which quantity is not stated, being here approximated):—

	Quant.
Placer gold (approximate estimate), oz.	4,000,0
Lode gold, oz.	2,952,6
Silver, oz.	54,648,7
Lead, lbs	613,914,0
Copper, lbs	415,353,9
Coal (net production, long tons), tons	32,429,1
Coke, tons	2,250,9

Quantities and value of mineral products for 1909 and 1910:—

	1909		1910	
	Quantity.	Value.	Quantity.	Value.
Gold, placer, oz.	.....	$ 477,000	.....	$ 540,000
Gold, lode, oz.	238,224	4,924,090	267,701	5,533,380
Totals, gold		$ 5,401,090		$ 6,073,380
Silver, oz.	2,532,742	1,239,270	2,450,241	1,245,016
Lead, lbs.	44,396,346	1,709,259	34,658,746	1,386,350
Copper, lbs.	45,597,245	5,918,522	38,243,934	4,871,512
Zinc, lbs.	.....	400,000	4,184,192	192,473
Totals, metalliferous		$14,668,141		$13,768,731
Coal, tons, 2,240 lbs.	2,006,476	7,022,666	2,800,046	9,800,161
Coke, tons, 2,240 lbs.	258,703	1,552,218	218,029	1,308,174
Totals		$ 8,574,884		$11,108,335
Other materials	.....	1,200,000	.....	1,500,000
Totals, non-metalliferous		$ 9,774,884		$12,608,335
Totals, metalliferous		14,668,141		13,768,731
Totals of yearly production		$24,443,025		$26,377,066

The foregoing table shows the production in 1910 as compared with 1909. In comparison with 1909, th following are the actual changes:—

	Quantities		Value	
	Increase.	Decrease.	Increase.	Decrease.
Gold, placer	.....	.....	$ 63,000	.....
Gold, lode, oz.	29,477	.....	609,290	.....
Total gold			$ 672,290	
Silver, oz.	.....	82,501	5,746	
Lead, lbs.	.....	9,737,600	.....	$ 322,909
Copper, lbs.	.....	7,353,311	.....	1,047,010
Zinc	.....	.....	.....	207,527
Total metalliferous			$ 678,036	$1,577,446
Coal, tons	793,570	.....	2,777,495	.....
Coke, tons	.....	40,674	.....	244,044
Other materials	.....	.....	300,000	.....
Totals			$3,755,531	$1,821,490
Less decreases			1,821,490	
Net increase			$1,934,041	

PRODUCTION OF MINERAL BY DISTRICTS AND DIVISIONS.

Names.	——Divisions—— 1909.	1910.	——Districts—— 1909.	1910.
Cariboo District	.....	.....	$ 247,000	$ 239,000

Coast Districts (Nanaimo, Alberni, Clayoquot, Quatsino, Victoria)	.....	.....	6,280,631	7,635,890
			$24,443,025	$26,377,066

The quantity of lode gold was the largest produced in any year by 12,119 oz., the largest previous production having been in 1908, 255,582 oz.

The silver was the smallest production of that metal in 15 years, the highest having been in 1897, of 572,971 oz.

The output of lead was the smallest in any year since 1903, which was the year payment by the Dominion Government of bounty on lead mined in Canada was commenced. The maximum quantity produced in any year since 1903 was in 1905, 56,580,703 lbs. Before that, however, the maximum in all years had been reached, namely, in 1900, with a production of 6,358,621 lbs, which was prior to the practical closing by a tariff impost of the United States market to Canadian lead.

The production of copper was the smallest on official record in five years. The maximum yearly output shown in the report was that of 1908, of 47,274,614 lbs. The comparison, however, may not be a fair one, since it is understood that previous to 1910 the official figures showed the copper contained in the ore, as estimated by assay value, not that actually recovered by smelting. As mentioned earlier, a deduction was made last year, at the rate of 5 lbs. of copper per ton of ore smelted, for loss in the slags, so the 1910 figures are nearer those of actual production of marketable copper.

The decrease in output of zinc was due to forest fires having destroyed surface plants at the mines of two of the chief producers of this metal, and, as well, burned bridges and trestles along several miles of railway, thus depriving those mines of transportation facilities, which have not yet been renewed.

The net production of coal shows a comparatively large increase—of 793,579 long tons. A comparison of the figures of gross production, that is, including the coal made into coke, is rather less favorable, showing an increase of 738,635 tons. The gross output of the two years, respectively, was: For 1910, 3,139,235 long tons; for 1909, 2,400,600 tons. The quantities made into coke were: In 1910, 339,189 tons; in 1909, 394,124 tons.

Other materials, that is, non-metallic minerals, practically all for building purposes, are credited with a 25 per cent. increase. It is most likely these have been underestimated in quite recent years until 1910, for there has been a steadily enlarging use of materials in building and road and footpath construction in the larger cities of the Coast district during several years, and this is continuing in larger degree than in the past.

The comment of the Provincial Mineralogist on this table, which shows the proportions of the total mineral production of two successive years made in each of the mining districts and divisions into which the Province is divided, is as follows: "It will be noted that this year, for the first time in many years, the Coast district has the honor of first place on the list, followed, in order of importance, by the Boundary and East Kootenay districts, while West Kootenay—for many years the greatest producer of mineral in the Province—is relegated to fourth place. The Coast and East Kootenay districts owe a considerable percentage of their output to the coal mines situated within their limits, whereas in the other districts the production is almost entirely from metal mining."

The total tonnage of ore was produced by the several districts in the following proportions: Boundary, 76.75 per cent.; Rossland (Trail Creek div.), 11.35 per cent.; Fort Steele div. (East Kootenay), 5.22 per cent.; Coast, 1.90 per cent.; others, 4.7 per cent.

Mines that Shipped Ore in 1910.

The number of mines from which shipments of ore were made in 1910 was 83, and of those only 50 shipped more than 100 tons each during the year, while but 32 shipped in excess of 1,000 tons each. Of the latter, 8 are in Nelson mining division, 8 in Boundary district, 3 in Ainsworth division, 4 in Slocan district, 3 in Coast district, 3 in Trail Creek (Rossland) division, 2 in Fort Steele division (East Kootenay), and 1 in Trout Lake division (West Kootenay).

The following table shows the number of mines that shipped ore in 1910; the districts in which they are situated; the tonnage of ore produced in each district; and the number of men employed, both above and below ground:—

	Tons of Ore shipped.	No. of Mines shipping.	No. of Mines shipping more than 100 tons in 1910.	Men employed in these Mines. Below.	Above.	Total
Cassiar:						
Atlin, Skeena & Queen Charlotte	4	1	..	4	4	8
East Kootenay:						
Fort Steele	115,762	5	3	229	84	313
Windermere-Golden	53	1	..	6	4	10
West Kootenay:						
Ainsworth	21,850	11	5	66	39	105
Slocan	44,466	20	11	220	79	299
Nelson	36,203	14	10	178	77	255
Trail Creek	253,471	9	5	492	149	641
Other Divisions	971	1	1	40	12	52
Boundary:						
Grand Forks, Greenwood, and Osoyoos	1,701,113	13	10	781	374	1,155
Ashcroft-Kamloops	12	1	..	6	3	9
Similkameen-Vernon	.....	..	..	..	..	..
Lillooet	443	3	2	9	4	13
Coast	42,080	4	3	143	104	247
Total	2,216,428	83	50	2,174	933	3,107

"An analysis of the above table shows, approximately, that, taking the Province as a whole, there were 713 tons of ore mined a year for each man employed about the mines. In this respect, however, the districts vary very materially, since, in the Slocan, the figures show 148 tons mined to the man in a year; in Nelson district, 142 tons; in Trail Creek, 395 tons; and in Boundary, 1,472 tons mined to the man employed.

"Such generalization, of course, does not apply exactly to any one mine, but only to the district, and in the first two districts mentioned the mines vary in charaeter so greatly, some having high-grade shipping ores and others low-grade concentrating ores, that care must be taken not to earry these average figures too far."

Non-Shipping Mines.

Another table in the report shows the number of non-shipping mines in each of the several districts, including those idle, together with the number of men employed. There are in all 153 of sneh mines, of which 56 were worked last year and 97 were idle. In those worked, 304 men were employed above ground and 298 underground; total, 602.

Men Employed in Mining.

The total number of men employed in mining in the Province—in both coal and metal mines—is as under. It should be explained that in arriving at these figures the eustom of the Department of Mines is, for instance, where 12 men are employed in a mine for 4 months, to count that as 4 men employed for 12 months, so that the total given is less than the actual number of individuals who worked in the mines during the year:—

In Metalliferous mines—	Above ground.	Under ground.	Total.
Shipping mines	933	2,174	3,107
Non-shipping mines	304	298	602
Total	1,237	2,472	3,709
In Non-Metalliferous Mines—			
Collieries	1,855	5,903	7,758
Grand total	3,092	8,375	11,467

Summary Review of Production.

Under the head, "Progress of Mining," the Provincial Mineralogist reviews at some length the production of the several minerals. Only a brief summary of his comments ean be given here, though.

Placer Gold.—Cariboo's production was $8,000 less than in 1909, due to a light snowfall the previous winter, the eonsequent shortage of water not admitting of all the sluices being cleaned up at the end of the gravel-washing season, so some of the gold had to be left in them for recovery in 1911 season. In Quesnel division of this district, the Quesnelle Hydraulic Gold Mining Co., of Philadelphia, Pa., made much progress with construction in connection with its water supply system for hydraulicking gold-bearing gravel, and expects to commenee mining next autumn.

In Cassiar distriet, $275,000 was recovered in Atlin division, which sum shows an increase of $75,000 over the recovery of 1909 season. The North Columbia Gold Mining Co. took about $150,000 out of its Pine Creek mines. The Guggenheim placer mine was leased to and worked by the North Columbia Co. The Pittsburg-British Gold Co., which controls McKee creek, also had a good season, but its operations were on a smaller scale than those of the North Columbia. The total yield of other parts of Cassiar distriet was smaller than in 1910.

Of the $18,000 recovered in other parts of the Province, $7,000 was from Lillooet district and $3,000 from East Kootenay.

Lode Gold.—To a total of $5,533,380, Rossland mines eontributed $2,465,455, Boundary $2,176,427, and Nelson (including Sheep creek) $761,359, all three showing increases over their production in 1909. About 76 per cent. of the lode gold is obtained from smelting ores and copper-bearing. The Hedley Gold Mining Co., operating a 40-stamp mill at Hedley, Similkameen (included in Boundary district), produced about $530,000 from the Nickel Plate group of mines. Two 20-stamp and several smaller mills in Nelson mining division recovered most of the lode gold credited to that division. There was a falling-off in the Coast and some other gold-producing districts.

Silver.—Slocan district, including Ainsworth and Trout Lake divisions, produced about 54 per eent. of the year's total output of silver, and Fort Steele mining

division 20 per cent., all from argentiferous galena. Forest fires in Slocan, and a lessened ore output from the St. Eugene mine, East Kootenay, combined to make the production of this metal smaller than in 1909. As result of development, the outlook is good for an enlarged production in 1911, chiefly from Slocan mines.

Lead.—As in other years, most of the lead produced came from Fort Steele division, East Kootenay. The following table shows the production of the several mining divisions:—

Mining Division.	Lbs of lead.	Percentage of total.
Fort Steele	23,874,562	68.88
Ainsworth	2,558,353	7.38
Slocan	6,406,358	18.49
Nelson	1,245,844	3.59
Trout Lake	463,295	1.34
All others	110,334	0.32
Total	34,658,746	100.00

Copper.—The next following table shows the copper production of the various districts for the last three years:—

District.	1908. Lbs.	1909. Lbs.	1910. Lbs.
Boundary	40,181,790	40,603,042	31,354,985
Rossland	5,042,244	3,509,909	3,577,745
Coast and Cassiar.	1,997,337	1,297,722	3,078,090
Yale-Kamloops	.....	.....	1,178
Nelson	53,243	186,572	231,936
Total	47,274,614	45,597,245	38,243,934

The proportions of production in 1910 were: Boundary, 82 per cent.; Rossland, 9.35 per cent.; Coast and Cassiar, 8.05 per cent.; Nelson, 0.60 per cent.

The average assays of the copper ores of the several camps, based upon copper recovered, were as follows: Boundary, 0.995 per cent.; Coast, 3.67 per cent.; Rossland, 0.705 per cent.

Zinc.—The total zinc output is from the Whitewater and Whitewater Deep mines in Ainsworth division, and the Lucky Jim and Van-Roi mines in Slocan division; there has not been any output from the zinc claims near Arrow Lake, nor those in East Kootenay. Forest fires last summer destroyed the surface plants of all but the Van-Roi, and the lease of the concentrating mill used by that mine expired in August, so there was no production of zinc at all during the latter part of the season. Shipments will be resumed after renewal of the destroyed plants and railway, and completion of the Van-Roi Co.'s new mill.

Other Minerals.—No iron ore was produced, there not being any iron blast furnaces in operation in the Province. Preparations to recover platinum in 1911 were being made, but none was obtained in 1910. Building materials showed substantially increased production. Drilling for oil was in progress in Sooke district, Vancouver Island. A deposit of oil shales, carrying a fair percentage of oil, has been found on North Thompson river, but this has not yet been proved of commercial value.

Work of Bureau of Mines in 1910.

The Provincial Mineralogist examined and reported on a small coal property in Boundary district; went to Wyne island and examined a deposit of crude pumice there; made a long trip to Tatlayoko lake, the headwaters of Homathko river, which flows into Bute inlet, and made a preliminary report as to its mineral probabilities; examined various mineral claims in Lillooet district, returning to the Coast by Pemberton meadows and Green lake; and subsequently examined the more developed mining properties on Boar river and tributaries, Portland Canal district.

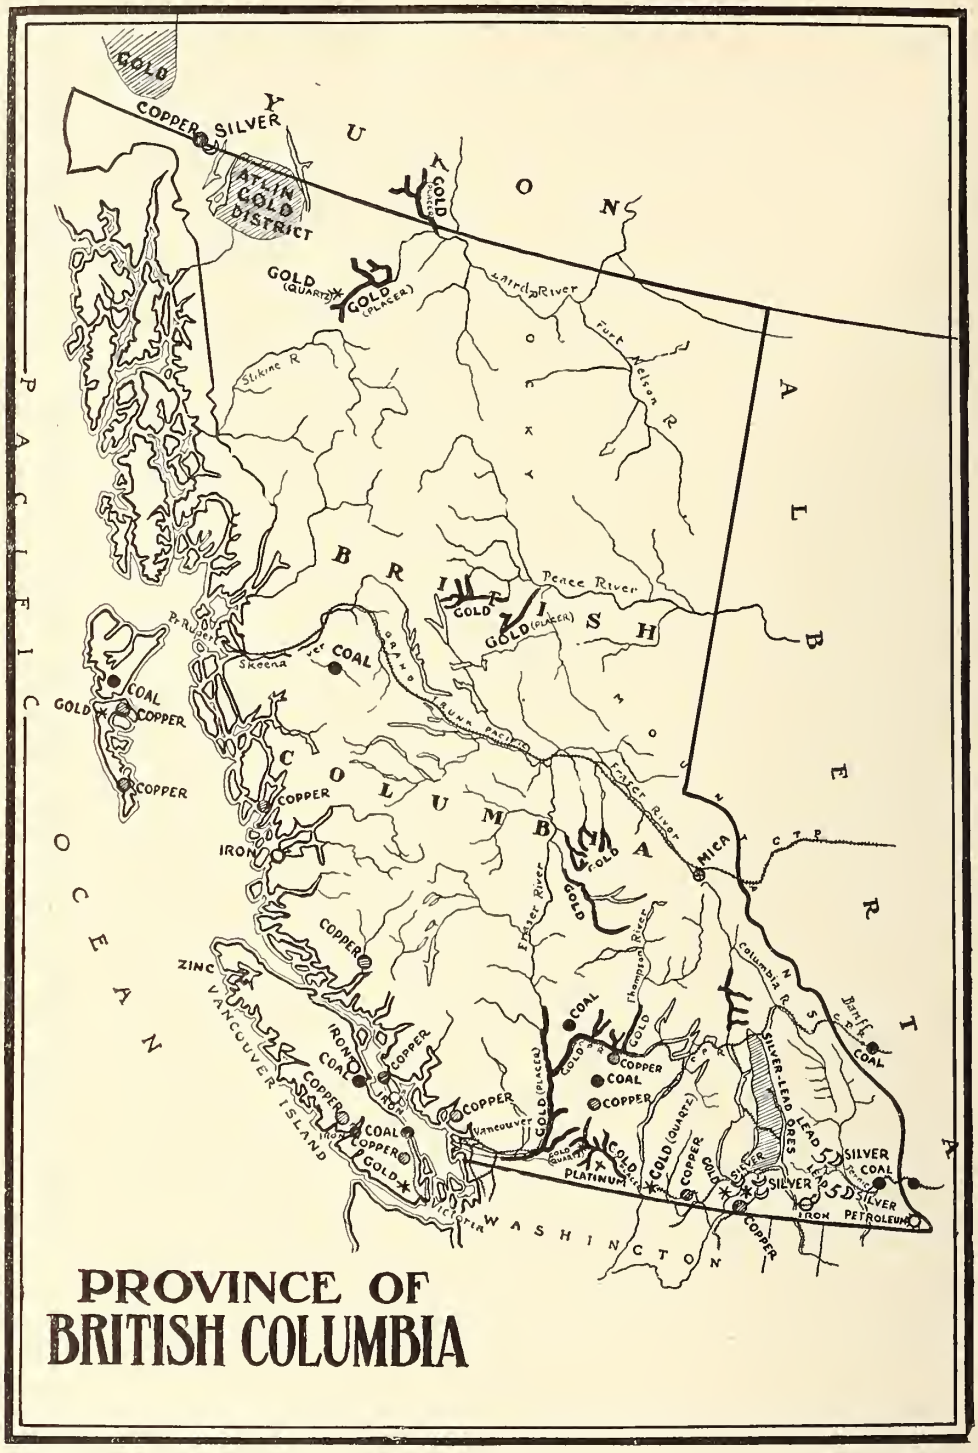
Two examinations for certificates of competency and license to practise assaying were held, in May and December, respectively, at the Provincial Assay Office, Victoria, and three candidates passed. Examinations for coal-mine officials—first—second—and third-class certificates—were held at Nanaimo and Cumberland, on Vancouver island; Merritt, in Nicola valley; and Fernie, Crow's Nest Pass. The total number of candidates was 78, as follows: For first-class, 20 (10 failed); for second-class, 20 (3 failed); for third-class, 38 (8 failed). Complete lists of licensed assayers and certificated coal-mine officials are printed in the Annual Report.

Reports of Mining Districts.

Reports of the Provincial Mineralogist and of the Gold Commissioners for the various districts and mining divisions fill 122 pp. of the report. Those on Cariboo district (including description of the Quesnelle Hydraulic Gold Mining Co.'s new hydraulic installation, in Quesnel division), Atlin division (with report of the Provincial Assayer on some rich gold-quartz claims on Taku arm); Portland Canal (with the Provincial Mineralogist's report on this division); Ainsworth, Slocan, Nelson (including Sheep Creek camp), Boundary, Lillooet (with the Provincial Mineralogist's special report), and Nanaimo (this last including reports by the Provincial Mineralogist on Tatlayoko district, and by the Provincial Assayer on Valdes and Lasqueti islands), are of much interest.

Inspection of Mines and Mine-Rescue Work.

The reports of the Chief Inspector of Mines and five district inspectors, respectively, give much information concerning the condition of both metalliferous and coal mines, lists and detailed statements of accidents in mines, etc. Information relative to mine-rescue work is also given by the Chief Inspector, who says: "It is very gratifying to be able to report that the several companies throughout the Province have responded very thoroughly to the statutory requirements of the Coal-mines Regulation Act as to the provision of mine-rescue appliances. The training of employees in mine-rescue work is progressing satisfactorily, though some difficulty is experienced in procuring a ready and economical supply of oxygen. The Hon. the Minister of Mines has caused enquiries to be made, with a view of establishing within the Province an oxygen-manufacturing and compressing plant, so that oxygen may be supplied readily and cheaply. This would seem to be absolutely necessary to efficiency and success. In addition to the colliery installations, the Department of Mines has established general installations of mine-rescue apparatus at Nanaimo and Cumberland (both on Vancouver island), Middlesboro (Nicola valley), and Hosmer (Crow's Nest Pass). Each of the various district inspectors of mines has graduated at a mine-rescue training course taken at the United States Mine-Rescue Training Station, at Seattle, Washington, and is consequently able to use, or direct the use of, the oxygen apparatus in an emergency." The Chief Inspector also gives a summary of the changes made in the Coal Mines Regulation Act when, last Spring, the act was consolidated and amended. In his introductory comments on this subject he says: "The various mining centres were visited by the Deputy Minister of Mines and the Chief Inspector, who held conferences with both the operators and the employees or their representatives. They re-



ceived numerous valuable suggestions, many of which were embodied in the completed bill, the main intent and purpose of which was to improve on the old act and introduce new measures for safety. Many valuable suggestions from the Report of the Royal Commission on Mines (Great Britain), 1906-1909, were also embodied in the bill, and upon all questions where any doubt existed the opinion of the Royal Commissioners was accepted as conclusive."

Miscellaneous Contents of Annual Report.

In addition to the contents already referred to, there is much other information contained in the Annual Report. Among other useful data are the lists of shipping mines, and of mineral claims Crown-granted in 19. A full index completes a report, which has been carefully prepared by the Provincial Mineralogist; illustrated by numerous excellent half-tone reproductions of photographs of country, surface works at mines and mills, and other appropriate subjects; also with maps, diagrams, graphic tables, etc.; and well printed at the Provincial Government Printing Office. The report is obtainable gratis on application to the Department of Mines, Victoria, B.C.

Notes on a Discovery of a Telluride Gold Ore at Opasatica, and its Probable Relation to the Gold Ores of the Porcupine and Neighbouring Districts.*

By Robert Harvie, Jr., Montreal.
(Transactions Canadian Mining Institute.)

In the course of a short examination of the geological conditions obtaining in the Opasatica district, undertaken by direction of the Quebec Department of Mines, the writer observed certain new points of interest which it has seemed well to present in correlation with information obtained in the not far distant and evidently similar districts of Ontario, namely, Larder Lake, Porcupine and Abitibi.

Relative Positions of the Districts.

The Opasatica district is in Quebec, on the height of land around the north end of Lake Opasatica, or about forty miles in a direction slightly east of north from the north end of Lake Temiskaming. From Opasatica, the Larder Lake district lies in Ontario about fifteen miles to the south-west, the Porcupine district is about 100 miles a little north of west, Abitibi is about fifty miles to the north-west.

As the general geology will not be discussed, this may be dismissed with the statement that the succession of Keewatin, Laurentian and Huronian is similar to that so frequently described for Cobalt and the other areas in this Temiskaming district.

Opasatica.—The gold is associated with quartz-ankerite fissure veins, although in one instance the ore body is a rusty weathering dike of a dioritie rock cut across by very numerous quartz veins, which carry the values. The country rocks are of Keewatin or Huronian age. The largest vein observed averaged about two and a half feet wide in an exposure of one chain in length, and it may be said that all of those examined hold their width well. The gangue is quartz, partly massive, partly in fine crystals, in both cases being commonly banded with ferruginous dolomite or ankerite and carrying sericite. In varying amount pyrite, chalcopyrite, petzite and free gold also occur. In some instances chalcopyrite forms a large proportion of the vein matter, and the wall rock on either side is also heavily charged with sulphides, probably chiefly iron pyrite.

The values are obtained both from free gold and from the telluride petzite, in which mineral there is about 24 per cent. of gold and 40 per cent. silver. The petzite was introduced later than the quartz and ankerite, being found in fractures in these minerals. The gold is chiefly in seams in the petzite. Petzite has a high metallic lustre of a steel grey colour, is heavy, has a low hardness, and altogether closely resembles galena, except that it lacks cleavage, and hence does not break into the cubes so characteristic of the latter. Owing to the small amount of work done so far, it is impossible to state what may be the relative importance of this telluride.

An assay of the pure chalcopyrite showed only half an ounce of silver and a trace of gold per ton; pyrite from the wall rock gave only 40 cents gold per ton. Apparently then, both these sulphides are unimportant as carriers of values.

*Larder Lake***—The gold is associated with irregular small quartz, or quartz and ankerite veins. The country rock is a rusty weathering rock consisting of ferruginous dolomite or ankerite, cut in a most complex manner by the gold-bearing veins mentioned above. In most localities it contains a large amount of chrome mica or fuchsite, from which the rock derives its characteristic green colour.

Porcupine.—The writer has not yet had an opportunity of visiting the Porcupine district, but the recent articles by R. E. Hore† seem to give an excellent account of the conditions, and his descriptions have been freely used for the present purposes.

The deposits at Porcupine are of various forms: single fissure veins, vein systems, large masses of irregular form, locally called "domes," and bands of carbonate rock so closely intersected by a multitude of small veins that the whole mass has to be mined together.

The country rock is usually either pyritie grey schist or rusty weathering mixed carbonates, belonging to the Keewatin. Less often it is a Huronian conglomerate. Serpentines also occur in the district.

The rusty weathering carbonate rocks are similar to those occurring at Larder Lake and contain the same green mica. The gangue is chiefly quartz and ankerite. In general the quartz is milky white and vitreous, but where it has been exposed to the weather it is coated with iron oxides. For a few feet from the surface, streaks and patches of this secondary material are found filling small cavities and crevices, evidently left by the weathering out of the ferrodolomite or ankerite. Pyrite is rather generally distributed through the quartz, but not in any great quantity. Copper pyrite is also found in small amount and occasionally galena and zinc blende. The gold occurs chiefly free, not only in minute fractures in the quartz, but more especially in the rusty cavities. It remains to be seen whether this seeming abundance in the cavities is actual, or only due to an apparent concentration as a residual after the weathering away of the ankerite.

Though no actual results have been published, it seems to be generally accepted that, while 50 per cent. to 65 per cent. of the gold is free milling, the remainder is held by the sulphides. On the other hand, mention is also made that "good assays have in several instances been obtained from very unlikely looking "bull" quartz." No report has yet been made of the presence of tellurides and it is quite possible, even probable, that having been overlooked they will account for the presence of gold in these veins.

Abitibi.—In the Abitibi district, in addition to other types of deposits, the rusty weathering carbonate rocks containing chrome mica, are typically developed, although on a small scale. The occurrence is quite close to a chromiferous peridotite.*

Significant Features.

Enough has probably been said in the above brief descriptions to show certain resemblances between the deposits of these four districts. More particularly, free gold is found in quartz ankerite veins in or near occurrences of a rusty weathering carbonate rock characterised by containing a bright green mica, and, while although so far tellurides have only been reported from Opasatica, still it seems probable that on closer examination they will be found in the other districts also. It is still more noteworthy that on these very same points an equally close parallel can be drawn with the deposits of the famous Mother Lode district of California. This will be done while considering a few special features in more detail.

Green Mica.—The beautiful bright green colour which the rusty weathering carbonate rock shows in so many places is due to a chrome bearing mica, fuchsite or mariposite. These minerals both contain chromium, but, in addition, mariposite also bears lithium. Mariposite is a very common mineral of the gold veins of the Mother Lode district in California.** Tests for chromium and lithium are readily obtained from the Canadian material and a rough comparison by the flame colouration test of the Larder Lake and Mother Lode materials shows the amount of lithium to be comparable.

The Carbonate Rock.—The rusty weathering carbonate rock has been given various names according to the origin to which it has been ascribed. In the Mother Lode district where similar masses of carbonate are found, it is now generally accepted that they are due to the carbonization of a serpentine or peridotite, intrusions of which are found in the district. Peridotite hydrated and oxidised gives a serpentine; serpentine carbonated gives magnesite, siderite, and quartz. This origin would seem best to explain the Canadian occurrences. Serpentines and peridotites are found at Porcupine and Abitibi, and are known to be widely distributed in the north country. Chromium, as is well known, is generally associated with peridotites so that the presence of the chromium bearing mariposite is explained and supports this view of the origin of the carbonate rock.

Ferruginous dolomites containing a chrome mica have been reported from Aird Island, near the Spanish River, in Lake Huron. This is suggestive of a wide distribution of these unusual rocks.x

Telluride Ores and Their Significance.

Among the minerals found in the Mother Lode ore are numerous varieties of tellurides. Although by far the greater proportion of gold won has been obtained free, yet in a few mines the tellurides have yielded very important amounts. This fact affords another interesting point for correlation, since, as was mentioned above, petzite, a gold-silver telluride, is found associated with the gold at Opasatica.

At Opasatica the free gold is found chiefly in fractures in the petzite, so that apparently here also, as has proved to be the case in other deposits of telluride ores, the telluride has precipitated the gold, but the evidence yet obtained is too scanty to warrant assertion as to whether or not this has given a secondary enriched zone. At Cripple Creek, Colorado, in the zone of oxidation above the level of the ground water, the gold occurs free, having been largely left behind during the leaching of the tellurides. Below ground water level, the tellurides have not been leached, and not only do they still contain their original gold content, but, in addition, they have caught and retained any free gold passing down in solutions from the zone of oxidation, thus causing an important secondary enrichment. The presence of tellurides at the surface at Lake Opasatica, indicates that the zone of oxidation has been removed by the heavy glaciation to which the district has been subjected. The present surface must therefore come either at the level of the zone of enrichment or below, but in either case from this argument, it seems unwarrantable to expect any great increase in values with depth, such as is regularly found to be the case in the mines of the Western States.

Tellurides have not been reported as yet from other districts, but it has been reported from Porcupine that some apparently unpromising veins have yielded good assay values, which values may well be due to the presence of tellurides. In other veins the free gold at the surface has been found to continue in slightly increasing quantity down to a depth of two hundred feet. It is quite impossible that in this instance the zone of oxidation has *not* been completely removed, in which case an enriched zone may be encountered beneath.

It may be mentioned that this is not the first discovery of a telluride in Eastern Canada. Petzite has been reported as occurring associated with argentite, galena, chalcopyrite and quartz in the gold ore of "Huronian Mine," near Lake Shebandowan, in Western Ontario.*

While it has not been decided what is the source of the gold and since, moreover, in the Mother Lode district, it is found that in general the serpentine or its products the carbonate rock is unfavourable to value it seems remarkable that, although some at least of the veins are of Post-Huronian age, still the gold seems to be most typically associated with Keewatin carbonate rocks. No explanation has been suggested for this.

Assaying and Milling.—The presence of tellurides complicates both the testing and the treatment of ores. The full value of the gold present cannot be judged from inspection or even by panning, because the amount contained in combination in the petzite is not shown by either of these processes. For this reason it is very essential that ores should always be tested by fire assay. Similarly when planning a mill, it must be kept in mind that simple amalgamation or cyaniding will not recover the gold and silver values of tellurides. The ore requires to be thoroughly roasted before employing these processes.

During the fiscal year ended June 30 last gold to the value of $10,273,000 was received at the United States assay office, Seattle, Washington. By far the greater part of this gold came from Alaska, but included in the total was $1,262,500 from British Columbia and Yukon Territory. As compared with the fiscal year ended June 30, 1910, there was a decrease of $1,858,000 in total value of gold received.

THE PORCUPINE FIRE.

By Alexander H. Smith.*

Porcupine, the first gold mining district in Ontario that has all the ear-marks of making good, has had more than its share of setbacks than it really deserves. The disastrous fire of July 11th, with its terrible toll of deaths by burning and drowning, must have saddened a large number who have taken an interest in its welfare and development.

Remains of Dome Plant.

For months the weather had been exceedingly dry, and numerous fires had destroyed timber and mining plants, culminating in the fires of the 11th inst. Sunday, the 9th, numerous fires were seen raging throughout the district, aggravated by a high wind from the south-west.

On Monday the wind was not so high, and the people felt more secure. On Tuesday a high wind started from the west, and by 11 a.m. was blowing a gale and increasing in violence every minute. From Porcupine Lake numerous heavy plumes of smoke could be seen in all directions, and everyone with a knowledge of forest fires in Ontario knew that the district was "in for it," and that stories of disaster were soon to come in after it was all over. No one, however, thought that such a terrible death list would be the result.

Shortly after 1 p.m. the Dome whistle was heard in South Porcupine, indicating that that part of the district was in danger. About 2 o'clock fire was sweeping south of the town of South Porcupine and people were hastily burying their belongings and escaping to the lake. Then the wind seemed to increase even more and heavy smoke swept through the streets and obscured the sun. The people from the outside and the village began to go out into the lake by canoes and launches, and even wading along the south side, where the water was shallow. Considerable confusion existed at the water front, and the explosion of a car of dynamite and black powder on the railroad siding to the south, about an eighth of a mile away, must have struck terror into many, who perhaps thought the end of the world had come.

Almost immediately the fire reached the village and drove into the water those who did not manage to get in a boat or had not started wading. The crowd skirt-

*Mining Engineer, South Porcupine, Ont.

ing the south shore were all safe, as the water was shallow, and one could wade out far from shore. Those in canoes were less fortunate, as many canoes were overloaded and capsized by a sea so high as to be almost inconceivable in such a small lake. During this time various detonations were heard, evidently magazines; and about 6 p.m. a very heavy shock, which proved to be a large magazine owned by the Hamilton Powder Co., situated a mile west of the town. By evening the smoke had cleared and a few houses at the little village of Pottsville and practically the whole of Golden City were found intact by those who had escaped from the south end. This was a blessing, as food and accommodation were to be had for most of the refugees. If Golden City had been destroyed the people would have starved until outside aid could have reached them.

Preston East Dome.

Dynamite Explosion.

Big Dome Mill.

Dynamite Explosion.

Wild rumours were pouring into Golden City, and, unfortunately, people were sure that most of them were all too true. The list of mining plants and buildings that were completely wiped out was known early on the morning of the 12th, and was as follows:—Vipond, Aura Lake Post-office, West Dome, Preston East Dome, Standard, Imperial, Dome, Philadelphia, and some smaller plants. Not a building was left at South Porcupine and Pottsville was almost completely wiped out.

The saddest part, however, was the terrible list of dead. The West Dome, where 20 were found dead in the shaft and four above ground; nine at the Dome; five at South Porcupine, and many known to be drowned in the lake added to the horror of the fire. Wild estimates were made, in which the numbers ran up into the hundreds, and naturally the question was put as to whether most of these deaths could have been prevented.

It is only just to say that in numerous instances the people did not realize the danger. For instance, at the West Dome the manager had successfully fought f round his buildings and plant a number of times. the Dome they did not realize that a terrific wind blowing, and they had confidence in their fire-figh appliances. When the smoke got thick people bec confused and ran in wrong directions for safety.

On the evening of the 12th numerous tents w pitched at South Porcupine. On the 13th five bod had been collected, and dead horses were cremated. ready men were stumping a lot in preparation for bu ing. Parties were scouring the woods trying to loc missing ones, and the lake was being dragged. Home and hungry ones were being looked after as well possible.

Men who can start things going so soon after suc calamity must be fighters, and naturally will take ri timid folk will not. It is just this fighting spirit t caused such a terrible loss of life. Numerous criticis were offered in respect to the terrible loss of life at West Dome. Was the management going to pack and get to safety and not leave a hand to save pl and buildings? The same holds good for the Dome a also accounts for some of the lives lost in South Por pine.

This is not going to be the last fire in the Porcup district, but it is to be hoped that it will be the wo and that it will teach some lessons that are badly need A small reservoir on the Dome provided a safe ref for many men. A narrow creek did the same for ma near the Preston East Dome. The small lakes on east side would do the same. This means that larger a more thorough clearings must be done round the min plants to secure their safety. The same country can burned over more than once, as the Hollinger Compa knows well.

storing of high explosives in a heavily-wooded ry like Porcupine is not properly understood. That load of blaek powder and dynamite was left on a in the traek of a roaring bush fire shows either npt for its contents, or carelessness on the part of ilroad not even excusable on account of the exigen- f eonstruetion.

effect of this explosion was most interesting, as by the rough sketeh; but it was the cause of one The Hamilton Powder Company's magazine was danger point, with the erudest fire proteetion. It e more eare was given to storage of explosives, he Government would do well to examine, say, the South African regulations in this respect. The best lesson given by the fire was to prove the buoyant disposition of the people, who commenced clearing up and getting things into proper shape before the embers had cooled down. As time passes and the clearings grow bigger danger from fires of this description will vanish; but that will not be for some time. A death list of over seventy, and the destruetion of so many valuable plants is a blow that would stagger even a well-established camp. That Porcupine, not two years old, should suffer such a blow is a calamity. As pointed out, however, she is strong enough to stand it and revive.

THE PORCUPINE FIRE.

By G. R. Rogers.*

ring the month of June and the early part of many fires were known to be blazing or smoulderin a south-westerly direction from Porcupine. On ay, July 2nd, a fire swept through a portion of ol Township; and, up to the time of the terrible aust, fires were raging in that section of the dis- In Tisdale, Deloro, and Whitney Townships fires were causing eonsiderable trouble.

ing to the extremely dry and excessively hot torrents of flame the many smouldering fires in the district. Judging from the extraordinary rapidity at whieh the fire was approaching, it was inevitable that all efforts to save South Porcupine from the flames were futile. Nevertheless, a number of men were out trying to block the fire, whieh they found impossible in the faee of the raging wind and heavy volumes of black smoke.

Information gathered from some of the parties sent out by the Relief Committee goes to show that the main

Fire in Porcupine, July 11.

her experienced during the two months previous to ire, it was realized that, should a strong wind arise, situation in Porcupine would be critical.

the morning of Tuesday, July 11th, a soft south- wind was blowing until noon. It then suddenly loped into a hurricane, travelling at a velocity of t seventy miles an hour, quickly fanning to roaring body of the fire originated in the eastern portion of the Township of Carseallen, or near the south-west eorner of Bristol, and, rapidly spreading itself into a zone from twelve to fourteen miles wide, travelled in a northeasterly direetion.

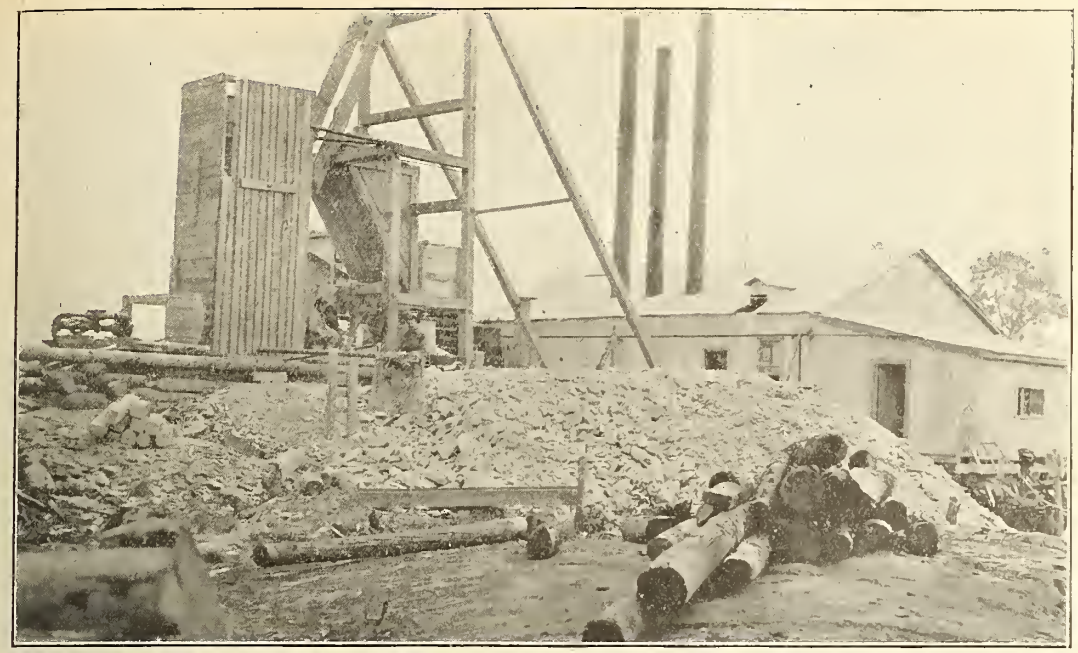
As nearly as ean be ascertained, the mines known as the "Standard," "Imperial," "Apex," "Dome Lake," "Preston East Dome," "West Dome," and the "Dome Mines" were in the centre of the fire zone.

Mining Engineer, 8 Torranee Avenue, Toronto.

Some idea of the rapidity with which the fire was driven before the furious gale may be gathered by the faet that scareely ninety minutes had elapsed from the time the plant of the "Poreupine Imperial Mines" was destroyed and the minute that South Porcupine and Pottsville were reduced to a smouldering bed of ashes, ineluding all the surface equipment and plants of the mines above mentioned. The "Hollinger," the "Rea Mines," the "Suceess Mines," the "Pearl Lake," and several others in the Gillies Lake seetion were saved from the fire. Not only did this fiery furnaee lap up with its hungry tongue of flame over two million dollars' worth of machinery and buildings, but it also carried with it the lives of a number of heroes who perished in a brave attem to save the property of their respeetive employers.

At South Porcupine and Pottsville men and w en stood at their posts of duty until the flames had al dy destroyed a number of shacks in the villages, and he fire eould be seen making its way at terrifie speed a ng the east shore of the lake in the direetion of G len City, and along the west shore to Pottsville. Realing that the battle against the devouring fire was lost, p- wards of a thousand terror-strieken people, inclu ng men, women, and children, made a wild rush to Po u- pine Lake, although the lake resembled a raging ea canopied with thiek volumes of black smoke, illumin ed

Bob Weiss, Wife, Child, Carlos Warfield, Tracy, and Millard at Weiss House, West Dome.



Last Picture Taken of West Dome, Main Shaft.

with ongues of flame that imparted the lurid colouring of a tropical sunset. But the lake afforded the only possible means of escape.

Gasoline launches, canoes, and hurriedly-constructed craft were quickly and willingly placed at the disposal of the women and children, who were taken to places of safety as soon as could be expected, considering that the men in charge of launches and canoes were working under appalling conditions. The manner in which the women and children were cared for can better be described by the fact that not one woman or child was drowned, while the lake is responsible for the deaths of several men, who lost their lives while endeavouring to cross the lake in canoes.

While hundreds of people were in the water of Porcupine Lake, waiting for the fire to complete its destruction in the villages, a car containing several tons of dynamite and a quantity of blasting powder, standing on a siding at Construction Camp 6, caught fire, causing the dynamite and black powder to explode, breaking many windows in Golden City, as well as blowing a hole fifteen feet deep and forty-seven feet in diameter in the soft earth.

The fire made its way along the west shore of the lake to Pottsville, and in less than fifteen minutes the village was completely wiped out. It worked its way round the north end of the lake, heading in the direction of Golden City. When it was seen that Golden City was in the path of the flames it was feared that an attempt to save the city would meet with results similar to those experienced in trying to save South Porcupine and Pottsville. However, a number of special constables were sworn in to keep order and assist the bucket brigade in fighting the fire to save, if possible, the only place of shelter left. The fire encircled Golden City with alarming rapidity, and it is only due to the indefatigable manner in which the many willing hands fought the fire that the new buildings in Golden City

Fire Wagons in Porcupine Lake.

were saved. All the buildings north of the Murphy House and north of the road, also a number on the south road that leads from the railway station, were burnt to the ground.

During the several hours of trial and terror, in which hundreds of terror-stricken people were engaged in saving each other from the merciless fire that left everything in devastation, upwards of seventy brave men and women perished from suffocation, drowning, or burning.

At the West Dome Mines, situated only five miles from Golden City, Robert A. Weiss, manager of the property, together with his wife and daughter, and seventeen others, including Mr. and Mrs. Burt, of Cobalt,

Golden Avenue, South Porcupine, Before the Fire.

Mr. and Mrs. D. M. McQueen, of Kippen, Scotland, were suffocated in the shaft, where they sought safety from the fire.

On the surface of the property, near the shaft, was found the body of William King, head prospector of the "West Dome," who remained at the shaft and sacrificed his own life in a brave attempt to save the lives of the twenty unfortunate people who were at the bottom. The bodies of four other men were found about the works in positions indicating the fact that they also died while endeavouring to save the property. The "Dome Mines," which is adjacent to the "West Dome," on the east, suffered loss by fire to the extent of its entire surface equipment, including the forty-stamp mill, which was in the course of erection, together with the lives of twelve men, who perished during the conflagration.

When word reached Golden City of the awful catastrophe at the Dome and West Dome Mines a number of men formed themselves into rescue parties and proceeded to the mines to assist those who were left on the property in the sorrowful task of extracting the bodies of the unfortunate men and women from the underground workings.

The following day a committee of seven men was formed, with Mr. Cyril T. Young, Ex-Mayor of Haileybury, as Chairman, for the purpose of taking care of the dead and injured; and, when addresses could be obtained, communicating with their friends and relations. Parties also were sent out in the different sections of the burnt area to search for those who were reported missing. This resulted in the recovery of several bodies that otherwise might not have been found.

Golden Avenue After the Fire.

Great credit is due Mr. Englehart, Chairman of the T. & N. O. Railroad Commission, for his prompt action in sending a special train to bring out the hundreds of people who were rendered homeless after the fire.

CANADIAN PATENTS

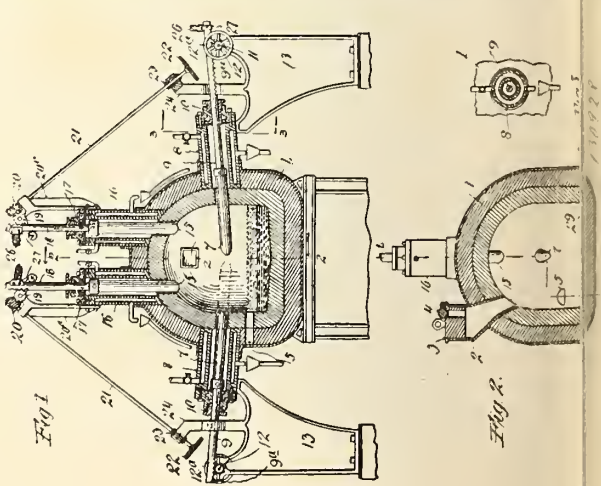
John W. Evans, Belleville, Ontario, Canada, 7th February, 1911, 6 years. Filed 14th January, 1911. Receipt No. 191,622.

Claim.—1. An electric furnace comprising a chamber, substantially horizontally disposed electrodes therein, a pair of separate electrodes independent of the first-named electrodes adapted to enter the material in the chamber, and means for operating said electrodes at will, the horizontal electrodes being arranged to produce an arc above the material in the chamber.

2. An electric furnace comprising a chamber, electrodes therein arranged to produce an arc above the material in the chamber, electrodes independent of the first-named electrodes adapted to enter the material in the chamber, and means for operating said electrodes independently.

3. An electric furnace comprising a chamber, a pair of electrodes adapted to produce an arc within said chamber, a separate pair of electrodes adapted to enter the material in said chamber, and means for individually operating said electrodes at will.

No. 130,928. Electric Furnace. *Four électrique*



4. An electric furnace comprising a chamber, electrodes adapted to extend across the same, and electrodes adapted to extend into the chamber at an angle to the named electrodes, one of the first and second-named electrodes being arranged to produce an arc between the second-named electrodes being arranged to heat the material in said chamber to pass electric current through said material.

5. An electric furnace comprising a chamber, substantially horizontally disposed electrodes adapted to enter said chamber to produce an arc, and a pair of electrodes arranged at opposite sides of the centre of the chamber and adapted to cross the path of the first-named electrodes, whereby an arc may be produced between one of the first and second-named electrodes and the second-named electrodes may enter the material to pass electric current through the same.

6. An electric furnace comprising a chamber, a pair of substantially horizontally disposed electrodes adapted to enter the chamber, and a pair of substantially vertically disposed electrodes adapted to enter the chamber and respectively aligned with the paths of the first-named electrodes, whereby arcs may be produced between one of the first and second-named electrodes at opposite sides of the furnace.

John W. Evans, Belleville, Ontario, Canada, 7th February, 1911; 6 years. Filed 14th January, 1911. Receipt No. 191,623.

Claim.—1. The method of reducing refractory material consisting in first applying heat to a body of material by an arc without the material to produce a molten mass, then cutting off such arc, and next heating said molten mass by passing electric current through a portion of the same.

2. The method of reducing refractory material consisting in subjecting the same to the action of an arc at approximately central portion of the body of material, subjecting said material to an arc at a distance from said central portion, and subjecting said heated mass to electric current passing through a portion of the same.

3. The method of reducing ore consisting in first subjecting a suitable ore mixture to the action of an arc to produce slag on the mass, then cutting off said arc, and next heating said mass by passing electric current through a portion of the same.

4. The method of reducing ore consisting in subjecting a suitable ore mixture to the action of an arc at an approximately central portion of said mixture to produce slag on the mass, subjecting said mass to an arc at a distance from said central portion, and subjecting said molten mass to electric current passing through the same.

5. The method of producing steel direct from iron ore consisting in first subjecting a mixture of iron ore, carbon and flux to the action of an arc to produce slag on the mass, then cutting off said arc, and next heating said molten mass by passing electric current through a portion of the same.

No. 130,929. Method of Reducing Refractory Materials.

Méthode de réduction de matériaux refractaires.

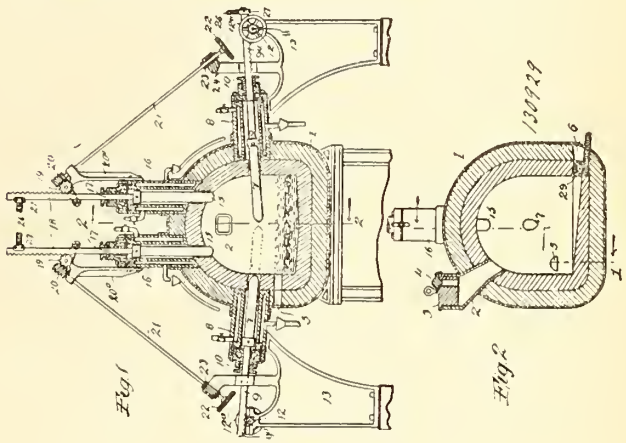


Fig 1 Fig 2

6. The method of producing steel direct from iron ore consisting in first subjecting a mixture of iron ore, carbon and flux to the action of the reflected heat from an arc at approximately the central portion of said mixture to produce a molten mass, subjecting said molten mass to an arc at a distance from said central portion, and subjecting said molten mass to electric current passing through the same.

7. The method of reducing refractory material consisting in first applying heat to a body of material by an arc to produce a molten mass, then cutting off such arc, and next heating said molten mass by passing electric current through a portion of the same, then cutting off said current and next refining said molten mass by applying heat to the same from an electric arc.

Voigt's Camp, Similkameen, B.C.
